34
35 15 **Abstract**

36
37 16 Among the most widespread forms of anthropogenic modification of the natural
38
39 17 landscape is road construction, with vehicle mortality a major issue affecting
40
41 18 amphibians, reptiles, mammals and birds. Why some species are more susceptible to
42
43 19 vehicle collision than others however is poorly understood. We examine how roadside
44
45 20 vegetation patterns, road size, vehicle speed and brain size influence vehicle avoidance
46
47 21 behavior using more than 3700 individuals of eleven species of European birds. We find
48
49 22 that on larger roads and at higher vehicle speeds birds were more likely to fly away
50
51 23 from the road than to cross it. Moreover, species with a larger relative brain size flew
52
53 24 away from the road more often than species with a small brain size, something that may
54
55 25 in part explain inter-species differences in vehicle collision mortality rates. Our results
56
57
58
59
60

1
2
3 26 provide important insights into factors that influence vehicle avoidance behavior in
4
5 27 birds and show that brain size can be an important trait for adjusting to novelties in
6
7 28 their environment.

33 **Introduction**

34 Road construction is among the most widespread and severe forms of human made
35 modification to the natural landscape (Forman and Alexander 1998; Fahrig and
36 Rytwinski 2009) and have well-documented negative effects on wildlife, including loss
37 of habitat, population fragmentation, pollution, poisoning and direct mortality caused
38 by collision with vehicles (reviewed in (Forman and Alexander 1998; Erritzoe,
39 Mazgajski, and Rejt 2003; Fahrig and Rytwinski 2009; Kociolek et al. 2011). In
40 particular collision with vehicles ('road kills') represents a considerable mortality risk
41 in many species of amphibians, reptiles, mammals and birds (Mumme et al. 2000;
42 Fahrig and Rytwinski 2009; Kociolek et al. 2011).

43 Theoretical models have clearly demonstrated that the least vulnerable
44 populations are those which show high vehicle avoidance behavior (Jaeger et al. 2005),
45 however empirical attempts to find the mechanisms behind why species vary in their
46 vehicle avoidance behavior are scarce. Variation in vehicle avoidance could be a result
47 of differences in external factors such as, for example, the speed of the approaching
48 vehicle or the type of road (Erritzoe, Mazgajski, and Rejt 2003), but could also be due to
49 interspecies differences in morphology (Brown and Bomberger Brown 2013), previous
50 exposure to vehicles (Mumme et al. 2000) or ability to judge vehicle speed and distance.

51 Several recent studies have demonstrated that species with a larger relative
52 brain size (i.e. brain size controlled for body size) are more successful when introduced
53 into novel environments (Sol et al. 2005; Sol et al. 2008; Sol et al. 2012), probably
54 because a larger brain can buffer individuals against environmental changes by
55 facilitating novel behavioral responses (Sol 2009). Variation in relative brain size
56 among species may therefore be one potential factor affecting the ability of species to

1
2
3 57 cope with anthropogenic changes such as vehicle traffic, which for many species
4
5 58 represents a novelty in their environments.
6

7
8 59 To examine what contributes to variation in vehicle avoidance behavior among
9
10 60 species, we collected data on more than 3700 individuals from eleven different species
11
12 61 of European birds. We asked whether the characteristics of the road and the
13
14 62 considerable variation in relative brain size among bird species (Iwaniuk and Nelson
15
16 63 2003; Sol et al. 2012) may contribute to among species variation in vehicle avoidance
17
18 64 behavior and therefore species vulnerability to vehicle collision (Jaeger et al. 2005).
19
20
21 65

22 23 66 **Materials and Methods**

24 25 67 *Data collection*

26
27
28 68 Data on vehicle avoidance behavior of individual birds were collected in Norway
29
30 69 along different types of roads in both rural and urban areas during the years 2003-
31
32 70 2010. While driving a vehicle, we recorded the flight direction of birds sitting on or near
33
34 71 the road when approached by the vehicle according to whether they flew away from the
35
36 72 road or if they crossed the road. Only birds that were observed before moving and that
37
38 73 were located on or within approximately 1 meter from the road verge (i.e. approx. 1
39
40 74 meter into the road from the verge and approx. 1 meter outside the road from the
41
42 75 verge) and that moved by flying were recorded. Birds located closer to each other than
43
44 76 approximately 100 meters were not recorded as the behavior of the first individual may
45
46 77 have influenced the behavior of the second individual. Similarly, for flocks (two or more
47
48 78 individuals in the same area) we only recorded the behavior of the bird closest to the
49
50 79 car, which was normally the individual that moved first. Birds that flew vertically up
51
52 80 from the road and crossed the road lanes at a height of more than approximately 3
53
54 81 meters were recorded as flying away from the road as these were assumed to be
55
56
57
58
59
60

1
2
3 82 outside the collision zone. Not all birds could be identified to species and these
4
5 83 individuals were excluded from the analyses.
6

7 84 Vehicle speed was categorized as being ≤ 50 km/h ($n = 1848$), between 50 – 80
8
9 85 km/h ($n = 1417$), or above 80 km/h ($n = 526$). The type of road was classified as major
10
11 86 paved road with heavy traffic ($n = 742$, road type 1), minor paved road with
12
13 87 intermediate traffic ($n = 1608$, road type 2), or gravel road with little traffic ($n = 1441$,
14
15 88 road type 3). The vegetation in the immediate vicinity of the road was classified
16
17 89 according to: i) similar height or no vegetation on both sides of the road (vegetation
18
19 90 type 1), ii) higher on the side where the bird was sitting compared with the other side
20
21 91 (vegetation type 2) or iii) lower on the side where the bird was sitting compared to the
22
23 92 other side (vegetation type 3). We categorized each species according to whether its
24
25 93 natural habitat was open landscape, semi-open or forest to control for between-species
26
27 94 differences in ecology and potential differences in exposure to vehicles.
28
29

30
31 95 Observations were collected in all months of the year, but the majority during
32
33 96 spring and summer (April, May, June, July and August together constitute 80 % of all
34
35 97 observations). To control for this we included season as a two level factor in the
36
37 98 statistical analyses (summer= April, May, June, July and August, winter = other months).
38
39

40
41 99 Data on body mass and brain mass were obtained from (Maklakov et al. 2011)
42
43 100 except for *Larus canus* and *Turdus iliacus* which were obtained from (Garamszegi,
44
45 101 Møller, and Erritzoe 2002) and (Møller, Erritzoe, and Garamszegi 2005) respectively
46
47 102 (sex-averaged values were used for *T. iliacus*). These are reported in Table 1 together
48
49 103 with number of observations.
50

51
52
53 104

54
55 105 *Reconstructing phylogeny.*
56
57
58
59
60

1
2
3 106 To control for shared ancestry of species we used a phylogenetic tree that was
4
5 107 constructed using sequence data from 12 mitochondrial genes (Thomas 2008). The
6
7 108 phylogenetic variance-covariance matrix was then used as a random effect in a Bayesian
8
9
10 109 phylogenetic logistic mixed model using the R package MCMCglmm (Hadfield 2010), see
11
12 110 statistical analyses.

13
14 111

15
16 112 *Statistical analyses.*

17
18
19 113 Test of departure from random vehicle avoidance behavior (i.e. 50% crossing the road)
20
21 114 for each species was done using exact binomial tests (Table 1). We tested for between-
22
23 115 species variation in the extent to which individuals fly away or crossed the road by
24
25 116 fitting species as a fixed effect in MCMCglmm. Because it is not possible to obtain an
26
27 117 ANOVA table from a MCMC object, we used a weighted Z-test (Zaykin 2011) to test for
28
29 118 among-species differences.

30
31
32 119 To test for a phylogenetic signal we compared a model with a phylogenetic
33
34 120 variance covariance matrix as random effect with a similar model including species as
35
36 121 random effect.

37
38
39 122 We examined how variation between species in their vehicle avoidance behavior
40
41 123 was related to road type, roadside vegetation pattern, vehicle speed, body mass, brain
42
43 124 size, season and the ecology of the species using Bayesian mixed models as
44
45 125 implemented in the R package MCMCglmm (Hadfield 2010; Hadfield and Nakagawa
46
47 126 2010) running 110,000 iterations with a burn in period of 10,000 and a thinning
48
49 127 interval of 100 and using uninformative priors. We checked that autocorrelation
50
51 128 between samples were less than 0.1.

52
53
54
55 129 The logarithm of brain mass and body mass were used as covariates in the model
56
57 130 (Freckleton 2002), which also controls for a positive relationship between body mass
58
59
60

1
2
3 131 and flight initiation distance in birds (Carrete and Tella 2011). Using 'relative brain size'
4
5 132 (residuals from a log-log regression of brain size on body mass) gave similar results
6
7 133 (see supplementary materials).
8
9

10 134

11 135 **Results**

12
13
14 136 When a vehicle approaches a bird sitting on the road, the bird can avoid it by
15
16 137 either taking the shortest distance away from the vehicle and fly directly away from the
17
18 138 road, or it can avoid the vehicle by flying across the road. Individuals that fly directly
19
20 139 away from the road will spend less time in the vehicle collision zone and have lower
21
22 140 mortality risk compared to individuals that fly across the road before leaving it. One
23
24 141 would therefore expect that most individuals fly directly away from the road rather
25
26 142 than cross it. Consistent with this we found that in all species, apart from *Larus canus*
27
28 143 and *Turdus iliacus*, a significantly larger proportion of individuals avoided vehicles by
29
30 144 flying directly away from the road rather than crossing it (Table 1). However, there was
31
32 145 significant variation between species in their vehicle avoidance behavior (weighted Z-
33
34 146 test: $P < 0.0001$). For example, whereas *Corvus monedula* avoided vehicles by flying
35
36 147 away from the road in more than 80 % of observations (Table 1), *Larus canus* did not
37
38 148 show any consistency in flight direction (52 % flying away from the road, Table 1). To
39
40 149 better understand this interspecies variation in vehicle avoidance behavior we tested
41
42 150 whether differences among species were related to characteristics of the road or due to
43
44 151 variation in brain size (corrected for body mass). Because a Bayesian phylogenetic
45
46 152 model to control for the shared ancestry of species had a higher Deviance Information
47
48 153 Criteria (DIC) compared to a model using species as random effect ($\Delta DIC = 0.79$), we
49
50 154 used a logistic regression mixed model with species (instead of phylogeny) as random
51
52
53
54
55
56
57
58
59
60

1
2
3 155 effect in the following analyses. However, using phylogenetic models gave same result
4
5 156 and estimates from the phylogenetic model are reported in table S1.
6

7 157 The best model included brain mass, body mass, road type, vegetation type, vehicle
8
9
10 158 speed and the species ecology, whereas there was no indication of differences in vehicle
11
12 159 avoidance behavior between summer and winter season (Table 2a).
13

14 160 The relationship between the probability that an individual will fly directly away
15
16 161 from the road and the relative size of the brain was positive (Table 2b), indicating that
17
18 162 species with a large brain relative to their body size generally avoided vehicles by flying
19
20 163 directly away from the road more often compared to species that had a small brain (Fig.
21
22 164 1). It should be noted that brain size and body mass are highly correlated in our data
23
24 165 both on observed ($r_p = 0.919$, $P < 0.001$) and on a log-log scale ($r_p = 0.966$, $P < 0.001$),
25
26 166 something which could cause co-linearity problems. To examine this we also analyzed
27
28 167 our data using relative brain size (residuals from a log-log regression of brain size on
29
30 168 body mass) and again found a positive relationship between probability to fly away
31
32 169 from the road and relative brain size (Table S2), indicating that the results are not
33
34 170 caused by problems with co-linearity. Moreover, there was a significant negative
35
36 171 relationship between body mass (controlled for brain size) and escape direction
37
38 172 indicating that species with a larger relative body mass crossed the road more
39
40 173 frequently compared to species with a small relative body mass.
41
42
43
44

45 174 Roadside vegetation pattern also had a significant influence on flight direction
46
47 175 (Table 2b). Although the probability of flying away from the road did not differ between
48
49 176 areas which had no or equal vegetation height on both sides of the road or where the
50
51 177 vegetation was higher on the side of the road from which the bird left, there was a
52
53 178 significant increase in probability of crossing the road if the vegetation was higher on
54
55 179 the opposite side to which the bird took off from (Table 2b). This suggests that at least
56
57
58
59
60

1
2
3 180 for some species seeking vegetation cover is an important escape strategy when
4
5 181 avoiding vehicles.
6

7 182 The type of road, classified as highway with high traffic volume, paved road with
8
9 183 intermediate traffic volume and minor gravel road with little traffic, also influenced
10
11 184 vehicle avoidance behavior: The probability of flying away from the road was
12
13 185 significantly larger on highways compared to the other two road types (Table 2b),
14
15 186 indicating that birds perceive the risk associated with crossing the road differently at
16
17 187 varying levels of traffic volume or road size.
18

19 188 As the speed of the vehicle increased so did the probability of a bird flying away
20
21 189 from the road (Table 2b). When testing each road type separately we found that this
22
23 190 was only true on minor roads ($b = 0.595$, lower-95% = 0.396, upper-95% = 0.834,
24
25 191 $pMCMC = < 0.001$) and gravel roads ($b = 0.358$, l-95% = 0.056, u-95% = 0.649, $pMCMC =$
26
27 192 0.02) and not on highways ($b = 0.077$, l-95% = -0.32, u-95% = 0.38, $P = 0.64$), possibly
28
29 193 because there is less variation in vehicle speed on highways compared to the other two
30
31 194 road types.
32
33
34
35

36
37 195

38 39 196 **Discussion**

40
41 197 Vehicle collisions constitute a significant mortality source for many animal species with
42
43 198 tens of millions of birds killed annually in both Europe (Erritzoe, Mazgajski, and Rejt
44
45 199 2003) and the United States (Erickson, Johnson, and Young 2005). However, we still
46
47 200 know little about why some species are more susceptible to vehicle mortality than
48
49 201 others. We show here that both characteristics of the road and relative brain size is
50
51 202 associated with vehicle avoidance behavior.
52

53
54
55 203 Why would species with a larger brain be better at avoiding vehicles? Previous
56
57 204 studies have found that individuals with a large relative brain size may have increased
58
59
60

1
2
3 205 cognitive ability (Sol et al. 2005; Kotrschal et al. 2013), although this is a controversial
4
5 206 issue (Chittka and Niven 2009; Sol 2009). A larger relative brain size may result in the
6
7 207 ability to judge vehicle speed and/or direction more accurately through increased
8
9
10 208 spatiotemporal information processing skills. In addition, a larger brain may also
11
12 209 facilitate vehicle avoidance through learning. Learning has been shown in Florida Scrub
13
14 210 Jays (*Aphelocoma coerulescens*) where immigrant birds with no previous experience
15
16 211 living next to roads have higher mortality than birds with such experience (Mumme et
17
18 212 al. 2000). It should be noted that the association between brain size and vehicle
19
20 213 avoidance behavior is based on a limited number of species, largely within the same
21
22 214 order (Passeriformes) and thus examining vehicle avoidance behaviour also in other
23
24 215 groups of birds is needed to evaluate the generality of this finding across the avian
25
26 216 phylogeny.
27
28
29

30 217 Vegetation along roadsides generally attract different animal and plant species
31
32 218 and have been extensively documented (Forman and Alexander 1998; Orłowski 2008).
33
34 219 However, roadside vegetation can also lead to increased mortality rates, for example in
35
36 220 birds who use it as an attractive place for breeding, resting and foraging (Erritzoe,
37
38 221 Mazgajski, and Rejt 2003; Orłowski 2008). Our results demonstrate that roadside
39
40 222 vegetation patterns can also influence vehicle avoidance behavior as there was a higher
41
42 223 probability for a bird to cross the road if the vegetation was higher on the opposite side
43
44 224 to which the bird was leaving from (Table 2b). In contrast, if vegetation was higher on
45
46 225 the side of the road where the bird was sitting the bird was more likely to fly away from
47
48 226 the road and this was also the case if there was no vegetation or when the vegetation
49
50 227 was of equal height on both sides of the road.
51
52
53

54
55 228 Not only roadside vegetation patterns altered vehicle avoidance behavior, also
56
57 229 the size of the road and hence traffic density were important determinants of flight
58
59
60

1
2
3 230 direction (Table 2b). It is well known that vehicle collision mortality rates in many
4
5 231 species of animals are higher on large roads with high traffic density (Forman and
6
7 232 Alexander 1998; Erritzoe, Mazgajski, and Rejt 2003; Orłowski 2008; Kociolek et al.
8
9 233 2011). That traffic density and road size should influence vehicle avoidance behavior is
10
11 234 therefore not surprising, birds were less likely to cross the road at major highways with
12
13 235 more traffic compared to smaller roads with less traffic (Table 2b). The differences in
14
15 236 vehicle avoidance behavior between road types could, for example, be a result of
16
17 237 habituation to vehicles on highways due to more frequent exposure to vehicles.
18
19

20
21 238 Another characteristic of the road that we did not examine here but that could
22
23 239 also play an important role for the vehicle avoidance behavior of birds is the age of the
24
25 240 road because this determines the amount of exposure birds have had with vehicle
26
27 241 traffic. As the study on Florida Scrub Jays demonstrates previous exposure to vehicles
28
29 242 can impact mortality patterns and it would be interesting to study the role of experience
30
31 243 on vehicle avoidance behaviour in more detail.
32
33

34
35 244 A larger proportion of individuals flew directly away from the road when the
36
37 245 vehicle speed was high compared to when it was low (Table 2b). This suggests that
38
39 246 birds adjust their vehicle avoidance behavior according to the speed limit of the car or
40
41 247 the speed limit in the area (we did not record speed limit in the area but of course these
42
43 248 two measures will be near identical). A recent study found that birds adjust their flight
44
45 249 initiation distance in relation to the speed limit of the road but not vehicle speed, with
46
47 250 longer flight initiation distance in areas where the speed limits were higher (Legagneux
48
49 251 and Ducatez 2013). Our study extends this work to show that also the direction in
50
51 252 which birds chose to leave the road to avoid being hit by a car is changing with vehicle
52
53 253 speed (and/or speed limits). Together our study and that of Legagneux & Ducatez
54
55 254 (2013) suggest that behavioral adjustments to anthropogenic changes can be flexible.
56
57
58
59
60

1
2
3 255 In summary, our results demonstrate that the size of the road, roadside
4
5 256 vegetation pattern and vehicle speed as well as brain size are important in determining
6
7 257 vehicle avoidance behavior. The positive association between brain size and vehicle
8
9
10 258 avoidance behavior is particularly interesting and support other studies that have found
11
12 259 brain size to be an important predictor for behavioral innovativeness and flexibility
13
14 260 (Lefebvre, Reader, and Sol 2004; Sol et al. 2012). The ability of different species to
15
16 261 adjust to anthropogenic changes in the environment may therefore in part be
17
18 262 determined by differences in the relative size of the brain.

340 **Table 1.** Species data for body mass, brain mass, number of records, number of observations of crossing versus flying away from the
 341 road and *P*-values from an exact binomial test if proportion crossing was significantly different from random (i.e. a proportion of 0.5).

342

Genus	Species	Family	Body mass (g)	Brain mass (g)	Observa tions	Crossed road	Away from	Binomial test
<i>Corvus</i>	<i>corone</i>	Corvidae	479.78	8.472	660	165	495	<0.0001
<i>Corvus</i>	<i>monedula</i>	Corvidae	214.39	4.840	262	49	213	<0.0001
<i>Pica</i>	<i>pica</i>	Corvidae	204.51	5.526	658	166	492	<0.0001
<i>Larus</i>	<i>canus</i>	Laridae	360.05	3.80	129	61	68	0.5975
<i>Emberiza</i>	<i>citrinella</i>	Emberizidae	28.65	0.822	264	112	152	0.0162
<i>Fringilla</i>	<i>coelebs</i>	Fringillidae	21.40	0.810	114	43	71	0.0111
<i>Motacilla</i>	<i>alba</i>	Motacillidae	21.11	0.598	655	263	392	<0.0001
<i>Sturnus</i>	<i>vulgaris</i>	Sturnidae	82.59	1.925	187	53	134	<0.0001
<i>Passer</i>	<i>domesticus</i>	Passeridae	27.70	0.970	131	39	92	<0.0001
<i>Turdus</i>	<i>iliacus</i>	Turdidae	65.20	1.215	110	58	52	0.6338
<i>Turdus</i>	<i>pilaris</i>	Turdidae	99.80	1.900	623	243	380	<0.0001

343 **Table 2.**

344 a) Model comparison of the Bayesian mixed models using species as a random effect. BS
 345 is the log₁₀ of brain size, BM the log₁₀ of body mass, RV is roadside vegetation pattern,
 346 RT is road type, VS is vehicle speed, E is the ecology of the species and S is the season
 347 the bird was observed (see Methods for further details). Best model is indicated in bold.

348	Fixed terms	DIC
349	BS + BM + RV + RT + VS + E + S	4566.34
350	BS + BM + RV + RT + VS + E	4564.76
351	BS + BM + RV + RT + VS	4565.52
352	BS + BM + RV + RT	4593.39
353	BS + BM + RV	4661.32
354	BS + BM	4672.16
355	BS	4673.01
356		

1
2
3 357 b) Summary of fixed effects from the Bayesian logistic mixed model that best explain the
4
5 358 probability to fly away from the road (from Table 2a). Estimate is the posterior mean,
6
7 359 LCI and UCI are the lower and upper 95% credible intervals. Terms are explained in
8
9
10 360 Table 2a.

361	Coefficient	Estimate (β)	LCI	UCI	pMCMC
362	Intercept	3.677	1.112	6.107	0.014
363	BS	2.921	0.888	4.649	0.010
364	BM	-2.125	- 3.515	- 0.634	0.012
365	RV_2	0.022	-0.221	0.238	0.890
366	RV_3	-0.552	-0.901	-0.193	<0.001
367	RT_2	-0.229	-0.497	0.065	0.114
368	RT_3	-0.599	-0.909	-0.294	<0.001
369	VS	0.415	0.268	0.564	<0.001
370	E_2	0.159	-0.339	0.634	0.438
371	E_3	-0.099	-0.694	0.444	0.714
