## Acknowledgement

This study was conceived and performed as MSc Environmental Toxicology and Chemistry at the Department of Chemistry in Norwegian University of Science and Technology (NTNU). I would therefore, first of all, like to thank the institution for the use of laboratory and apparatuses.

I express my sincere thanks to my supervisor Trond Peder Flaten for all his advices both during the process of working on the thesis as well as sample preparation and analysis. I am sincerely grateful to my co-supervisor Alexandros Asimakopoulos for the mentoring on both lab work and data analysis.

I would like to be thankful for the help of Susana Villa Gonzalez and Kristine Vike in method development for LC-MS/MS. I would also like to thank Syverin Lierhagen for all of ICP-MS related work. A special thank also to Vishwesh Venkatraman providing principle component analysis.

Finally, I would like to appreciate all support and encouragement of my family, friends and co-students.

Trondheim, 15.05.2019

Yuki Kimura

#### Abstract

Processed food stuffs are added chemicals to keep stable quality for long periods. While the additives give positive effect to ordinary life, some of these also possibly cause estrogenic problem for our health. Therefore, determination of the quantity of those chemicals in the food stuffs is a very important task. Among food stuffs, snacks are popular in all generations all over the world, however it has not studied yet. Focusing on the snack food stuffs, thus, would provide useful result for choosing it for especially infants who should be cared for health. Comparing the trend by countries and by food types should be emphasis.

In this study, a liquid chromatography tandem mass spectrometry method was developed and employed for the simultaneous determination of six parabens, five parabens derivatives and an antimicrobial in the snack food stuffs. The target parabens were methyl paraben, ethyl paraben, propyl paraben. butyl paraben, benzyl paraben and heptyl paraben, target parabens derivatives were 4-hydroxybenzoic acid, 3,4-dihydroxybenzoic acid, 4-hydroxy-3methoxybenzoic acid and ethyl-protocatechuic acid, and target antimicrobial was triclocarban. Methyl paraben and ethyl paraben are well known preservatives, while derivatives are previously suggested transformation process from parabens within an organism. In addition, 62 elements were measured in the snack food samples by ICP-MS analysis in order to account for inorganic pollution sources.

The snack food samples analyzed in this study were collected at the markets in seven countries. Solid-liquid extraction was employed for clean-up and extraction process. For concentration, parabens derivatives were basically much higher than parabens, whereas antimicrobial, triclocarban, was presented very low value over all samples. Methyl paraben and ethyl paraben were the most popular preservatives used, but heptyl paraben was only found in low concentrations. No clear between country patterns were found possibly due to international trade. For categorized characteristics, clear difference was found. Further, in the inorganic analysis, accuracy was $\pm 20 \%$ as certified reference materials and parallel/repeating test. Macromineral elements were presented the highest concentration, then trace elements followed. The result also indicated the snacks contained different ingredients depending on the country.

In the PCA analysis, results were separated by characteristics, form, taste and target age. Na and EtP/OH-EtP were positively correlated, which can be a marker to know how amount of EtP would be contained as seeing the product package.

| Methanol | MeOH |

## 1. INTRODUCTION

## 1. INTRODUCTION

Nowadays, most consumer products all over the world are mass produced and packed for long term preservation. To achieve this, several different chemicals are added. Paraben ( $p$ hydroxybenzoic acid esters), Triclosan (2,4,4'-trichloro-2-hydroxydisphenyl ether) and Triclocarban (3,4,4'-trichlorocarbanilide) are some of them which are used for long period preservation due to their antimicrobial properties. These are group of chemicals generally used as additives in foodstuffs, beverages, cosmetics, pharmaceuticals and several personal care products (Andersen 2008; Guo and Kannan 2013; Karthikraj and Kannan 2018; Moreta et al. 2015a). Those chemicals have also been considered as pollutants due to their specific property.

Recent studies have focused on the amount of parabens in human urine (Adoamnei et al. 2018; Casas et al. 2011; Honda et al. 2018; Iyer et al. 2018; Zhao et al. 2017). Knowing the pollution level is important to avoid pollutants, as well as improve the principle of pollutant use. While, the possible sources of pollutants were also studied so far; how amounts of parabens contained in the indoor dust, baby goods, foods and pharmaceuticals (Asimakopoulos et al. 2016; Chen et al. 2018b; Liao et al. 2013a, 2013b; Ma et al. 2016; Moreta et al. 2015b). These reported that possible sources where people were exposed to pollutant, and how concentration of them were detected. Among them, especially food analyses are really important subject since we have to ingest for life, however the studies were done by comparing the stuffs in a country. Evaluating the differences between country to country will be useful study to know the trend of use in country and possibly take the first step toward improving the regulations for use of pollutant for our health.

In addition to the above, elemental analysis is also needed as some elements are essential for our health and some are toxicity. Elemental analysis of food have been performed in many countries, but few studies have been carried out with comparing different countries (Chekri et al. 2019; Fátima Barroso et al. 2009; Moreda-Piñeiro et al. 2018), and few studies have been carried out on snacks which are eaten between meals. Therefore, in the present thesis both organic and inorganic chemicals have been determined in a wide variety of popular snacks collected in several countries, with a focus on possible differences between countries and the interrelationships between organic and inorganic components.

## 2. THEORY

## 2. THEORY

The theory part begins with the properties of organic chemicals which are target analytes (parabens, its derivatives and microbials) in this study, and possible uses and effects. Then, inorganic chemicals section gives a description of properties of elements, possible sources and effect to human. A brief description of sample preparation follows, as well as analytical techniques which were employed in this study. Thereafter, detailed description is provided for quantification and quality assurance/validation. For the statistical process of data, theory about data transformation, correlations and principal component analysis (PCA) is presented in the last.

### 2.1. Organic Chemicals

### 2.1.1. Parabens

The parabens are the ester compounds of PHBA (4-hydroxy benzoic acid, 4-HB) and there are various kind of substituent which are attached as esters. The alkyl chain and aromatic ring are often put on there. Commonly known parabens are Methyl paraben (MeP), Ethyl paraben (EtP), Propyl paraben (PrP) and Butyl paraben (BuP), Heptyl Paraben (HeP) which are the example of parabens with alkyl chain, while Benzyl paraben (BezP) is representative paraben having aromatic ring (Figure 2.1).

Butyl paraben

Ethyl paraben

Benzyl paraben

Propyl paraben

Heptyl paraben

Figure 2.1: Chemical structure of parabens ring

Parabens are added commonly in foodstuffs because of their properties such as their stable over wide pH , lack of taste and odor, unchanged color, solubility in water and non-volatility (Ito et al. 2015; Soni et al. 2005, 2002). Moreover, the combination of multiple parabens can enhance the antimicrobial activity (Soni et al. 2002). There are several kinds of benefit as additive for products, however weak estrogenic activity attributed to some of them have been indicated. Various bioassays have reported that MeP, EtP, PrP, BuP and BezP possess estrogenic properties(Ahn et al. 2012; Anne Marie Vinggaard et al. 2000; Darbre et al. 2002; Golden et al. 2005; Hossaini et al. 2000; Hu et al. 2013; Miller et al. 2001; Oishi 2002; Okubo et al. 2001; Routledge et al. 1998). From this perspective, an acceptable daily intake (ADI) for the total amount of three parabens, MeP, EtP and PrP, has been set up at $<10 \mathrm{mg} / \mathrm{kg}$ body weight (bw)/day (JECFA 1974). Further, the use of PrP and BuP for children's product was prohibited in Denmark in 2011 (SCCS 2011).

Other kinds of chemicals with structures similar to parabens are also a focus in this study. 4hydroxybenzoic acid (4-HB), 3,4-dihydroxy benzoic acid (3,4-DHB), 4-hydroxy-3methoxybenzoic acid (Vanillic acid) and ethyl-protocatechuic acid (OH-EtP) are showed below (Figure 2.2). 3,4-dihydroxy benzoic acid is also known as protocatechuic acid which is a phenolic compound. It is often found in natural products such as flowers, fruits and plants and used as additive due to its applications: antioxidant, antiulcer and antidiabetic. Moreover, antibacterial and antiviral activities are reported as function of 3,4-DHB (Antony and Wasewar 2018). While Vanillic acid is also used for food and drug products as flavoring agent and an intermediate of the vanillin. It is the plant product having cardioprotective, antimicrobial and antioxidant properties (Antony and Wasewar 2018; Rasheeda et al. 2018).

### 2.1.2. Antimicrobials

Triclosan (TCS) and Triclocarban (TCC) are categorized as polychloro phenoxy phenols
(Figure 2.3). These two compounds are often used as antimicrobials for personal care

## 2. THEORY

products (PCPs). Regarding TCS, it has been incorporated into polymeric materials for packaging to reduce or prevent microbial growth (Espitia et al. 2016; de Fátima F Soares et al. 2009). Recent studies have shown the potential health risks which TCS constricts endocrine and immunological ability such as improvement of bacteria resistance and cancer (Dinwiddie et al. 2014; Schweizer 2001). Under these circumstances, TCS has been removed from the EU list of provisional additives for use in food contact materials (Dann and Hontela 2011). As for TCC, it can impair mammalian reproduction and the methemoglobinemia is related with exposing human (Asimakopoulos et al. 2014; Zhou et al. 2012).

Triclocarban

Figure 2.3: Chemical structure of microbials

### 2.2. Inorganic Chemicals (Heavy Metals)

Heavy metal $(\mathrm{Cd}, \mathrm{Cr}, \mathrm{Cu}, \mathrm{Pb}, \mathrm{Ni}, \mathrm{Hg}$ and Zn$)$ contamination has been getting major concern in worldwide scale because of a serious threat with their duration, concentration and toxicity (Sang et al. 2018; Santorufo et al. 2012). The possibility of heavy metal's accumulation in food crops has been increased due to natural and human activities such as mining and metal smelting, urban development and injudicious use of agricultural chemicals (Doabi et al. 2018; Huang et al. 2007; Wu and Yi 2015). There are mainly three routes which heavy metals are transferred into human body: ingestion, inhalation and dermal contact (Aelion et al. 2008; Doabi et al. 2018; Madrid et al. 2002; Qing et al. 2015; Wu et al. 2015). Due to the serious toxicity, some heavy metals may pose a problem even at low concentrations. In Japan, for instance, cruel incident related heavy metal has occurred around half a century ago. Mercury contaminated effluent was discharged directly to ocean without any cleaning up process, therefore chemicals related mercury had been accumulating in environment. As a result, lots of people were exposed to potent toxicity (Evers et al. 2016; Tomiyasu et al. 2014). The heavy metals are also included in food waste and have effect to waste treatment. Possessing acute toxicity, substantial treatment costs are taken and it has financially stressed to cope with the treatment process in government across different countries (Chu et al. 2019).

### 2.3. Sample Preparation

Many challenges are involved in trace analysis of samples because there are the complexity of sample matrices and the diversity of interfering compounds (Pérez-Fernández et al. 2017). The performance of selected procedure for sample preparation might have impact due to existence of the matrix: the limit of detection, the limit of quantification, accuracy, precision and linearity might get effect. Because of quite low concentration of environmental samples, enrichment and clean-up process are needed as pre-treatment procedure to achieve suitable concentration level for analysis (Padrón et al. 2014). There are several objectives which should be accomplished for sample extraction toward coming analysis. Primary, the separation of the target chemicals from complex matrix is essential task such as foodstuffs samples to remove interfering compounds. Secondary, in case of trace level analytes, the target chemicals should be condensed to improve instrumental sensitivity applying extraction and concentration steps. Lastly, consideration for the compatibility between the apparatus analysis and the sample matrix is necessary step. Mass spectrometry is the most common technique for organic and inorganic compounds detection (Mitra 2003).

### 2.3.1. Sample preparation for organic chemical analysis

This section explained the extraction methods for organic analytes, as well as the analytical techniques performed by the earlier researches is given in Table 2.1.

### 2.3.1.1. Liquid-liquid extraction

Liquid-liquid extraction (LLE) is an appropriate method separating between two immiscible solvent such as organic solvent and aqueous solution. In the simplest case, the solute, the carrier liquid and the solvent are involved. This extraction technique is known as safe, reasonable way and environmentally friendly process. The partitioning coefficient $K_{L L E}$ is given by the equation:

$$
\begin{equation*}
K_{L L E}=\frac{[\text { analyte }]_{\text {organic }}}{[\text { analyte }]_{\text {aqueous }}} \tag{2-1}
\end{equation*}
$$

[analyte] $]_{\text {organic }}$ and [analyte] $]_{\text {aqueous }}$ are showing the concentration of the analyte in the immiscible phase (Lundanes et al. 2014; Marsousi et al. 2019).

## 2. THEORY

### 2.3.1.2. Solid-liquid extraction

Solid-liquid extraction (SLE) is similar to LLE except that the solute dispersed in a solid phase rather than in a carrier liquid. This classical extraction method can separate analyte from solid samples into liquid phase then solid sample is removed by filtration. The efficiency of this extraction technique is mainly affected by solvent, time of contact, temperature, solid/liquid ratio (Ballesteros et al. 2013; Lepojević et al. 2017).
In recent years, there are several assisting techniques for increasing efficiency of extraction procedure such as ultrasound-assisted and pressure-enhanced methods. Ultrasound-assisted is an effective and time-saving extraction method. It is suitable way for temperature-sensitive components since it can reduce the operating temperature. Whereas, pressure-enhanced can increase the extract yields with shorter time at lower temperature and enhance mass transport process. It has also been recognized as an environmentally friendly technology (Baranowska 2016; Xi and Luo 2015).

## 2. THEORY

### 2.3.2. Sample preparation for elemental analysis

A decomposition is essential process for inorganic analysis to put the original sample into a solution where the analyte is homogeneously distributed prior to instrumental analysis. The principle of an effective procedure is that dissolution must be performed as complete as possible, organic materials have to be absolutely mineralized and inorganic materials should be altered to soluble compounds. Residual matrix components must be removed to prevent them from interfering with the detection (Baranowska 2016). Liquids can be analyzed directly without decomposition provided total dissolved solids (TDS) are below $0.5 \%$, whilst the solids can precipitate in the nebulizer overloaded plasm when TDS is above $0.5 \%$. With solid samples containing the organic matter have hydrogen peroxide added during dissolution step due to the property of $\mathrm{H}_{2} \mathrm{O}_{2}$ breaking down organic matter efficiently ("Thermo Fisher Scientific" 2019a).
Microwave-assisted acid digestion has been considered as the most suitable method for the decomposition of complex matrices. Taking advantage of several aspects, that sample preparation technique using various combination of acids under high temperature and pressure has become well established and an extensively employed process for digestion of assorted food related matrices to determine the metals (Mullapudi et al. 2019). This process can make digestion time shorter and recovery better even for volatile elements and it decreases the risk of external contamination. The detection limit and the accuracy of the analytical method are improved since even the small amount of acids is enough (Hassan et al. 2007). Nitric acid is strong oxidant which can dissolve all common metals except aluminum and chromium (Skoog et al. 2003).

### 2.4. Analytical Techniques

### 2.4.1. LC-MS/MS

### 2.4.1.1. Principle

A mass spectrometer coupled to HPLC (LC-MS/MS) is a common apparatus to analyze the samples as it has good property of robustness, automation and performance (Lundanes et al. 2014). The combination of LC and MS provides high sensitivity and "fingerprint" of a specific eluent instead of depending on the retention time in HPLC (Skoog et al. 2003). The important part of the LC analysis system is the chromatographic column which the actual separation occurs (Figure 2.4). The ability of the column separating the samples in the complex matrices must be considered. The efficiency of the separation of the different analyte
from each other is also considerable point to avoid and decrease the background noise in the analysis. Likewise, it is possible to reduce the risk of false positive and negative results (Kuster et al. 2009). The HPLC can separate the compounds relying on the different polarity.

The HPLC system consists of the various components which have different tasks to perform the analysis (Figure 2.4). First of all, the mobile phase is pumped up into the injector and the samples are simultaneously introduced into the injector. At there, samples are dissolved into the mobile phase and transferred to the column. The column is the place where the separation of the individual ingredients occurs depending on the different polarity of the components (Lundanes et al. 2014). The important factor to obtain clearly separated peaks in LC is the composition of the mobile phase and the column design/type (Fernando 2013). When the analytes have been separated into individual components, the various kinds of components are detected. After separation, the separated peaks are flowed into the detector. A typical LC column is $15-25 \mathrm{~cm}$ in length with 2-5 mm internal diameter (Lundanes et al. 2014). The most popular tube packing for LC consists of the small silica particles which is average 3-10 $\mu \mathrm{m}$ as diameter (Skoog et al. 2003). Effecting the variety of interactions between the components in the sample and the stationary phase in the column, each component elutes at a different speeds and different retention times. Retention time is the time from the sample injected into the mobile phase until selected peaks observed at the detector (Lundanes et al. 2014). To improve the peak shape in chromatography, the acidic condition for the mobile phase is the most effective way with mixture of methanol-water or acetonitrile-water with gradient elution. Furthermore, adding the acetic acid, formic acid or ammonium acetate into the mobile phase to get modification is powerful attempt improving the sensitivity of MS detection (Fernando 2013).

Figure 2.4: General instrumentation of HPLC system ("LaboratoryInfo.com" 2018)

## 2. THEORY

In this experiment, a tandem mass spectrometer (triple quadrupole) was employed for the detection and quantification of target analytes. To identify all the components existing in the chromatogram of effluent, the information of molecular weight and retention times obtained from the total ion chromatogram of a mass spectrometer is usually not enough. However, a LC-MS/MS system can provide a superior sensitivity than can be provided by mass range scan since that system can produce the daughter ions by collision-induced fragmentation of the molecular ion. The fragmentation from the molecular ion to the daughter ions is attributed to the fragment-induced cleavage and rearrangements due to the missing of neutral molecules. Examining the mass intervals and isotopic patterns between product ions, the structure of the daughter ions can be estimated (Marvin C 2005).

Figure 2.5: Schematic of a triple quadrupole mass spectrometer (Marvin C 2005)

The triple-quad LC-MS/MS (Figure 2.5) is designed to cleave ions into their daughter ions. It consists of 3 quadrupoles: a scanning Q1 quadrupole analyzer for separating the original precursor ion, an un-scanned Q2 quadrupole that serves as a collision cell to fragment the ions sent to it by collision with a heavy gas molecule and a scanning Q3 quadrupole analyzer for separating the fragments generated in the Q 2 section. The first quadrupole (Q1) is operated in a full-scan or SIM mode to select ions to transfer into the Q2 quadrupole. The middle Q2 is filled with an inert heavy gas like krypton or xenon and the fragmentation is brought on as the transferred ions from Q1 to Q2 where the collision undergoes with the inert heavy gas. The last analyzer Q3, likewise, can be performed in full-scan or SIM mode operation (Marvin C 2005).

There are four possible combination mode of the two analyzers (Q1 and Q3): Q1 for scan/Q3 for SIM that is daughter mode/precursor scanning; Q1 for SIM/Q3 for scan that is parent mode/product scan; both Q1 and Q3 for scan called neutral loss scanning mode; both for SIM referred to multiple reaction monitoring (MRM) mode. The operation with the scan/SIM
mode can determine which primary fragments are related each other. The Q1 is scanned over the mass range, then all fragments are transferred to the collision cell (Q2) and cleaved to the secondary fragments. The Q3 focuses on a specific mass/charge position and only primary fragments which break down to a specific secondary $\mathrm{m} / \mathrm{z}$ value will be detected. The common daughter ion indicates interrelated primary fragments and becomes clue to understand easily which fragment are formed when a large primary fragment cleaves. On the other hand, the SIM/SIM combination is applicable to analysis for the specific components containing very impure mixtures without the complete clean-up process. The analysis can be performed at very high sensitivity as both analyzers detect at different specific single $\mathrm{m} / \mathrm{z}$ values, and a lot of scans can be summed in determining their positions. When examining the chromatographic peak which are expected to appear, the first quadrupole separates a primary fragment characteristic of the targeted compound, it is passed to the collision cell then, the third quadrupole identifies it by looking for only one of its specific daughter ions at last. As for each analyzed compounds, an individual primary and secondary fragment in a time basis is picked up with corresponding the expected chromatographic retention time (Marvin C 2005).

### 2.4.1.2. Electrospray ionization

Electrospray ionization (ESI) is one of the well-known techniques for LC-MS and applicable to wide range of analysis. ESI is executed under the atmospheric pressure and mainly eligible for polar compounds. Neutral components either accept or donate a proton to generate positive or negative ions under given conditions. This reaction can occur either in the mobile phase or during the ESI process. The ionization process for acids and bases happens in the mobile phase with pH adjustments (Lundanes et al. 2014).
In this method, the mobile phase containing the analyte moves into the capillary with high voltage (typically +5 or -5 kV ). A nebulizing gas $\left(\mathrm{N}_{2}\right)$ is mixed with the mobile phase at the outlet of the capillary and it is facilitated to form the droplets. A dry gas is introduced oppositely against the direction of flow. The droplets explode into smaller droplets due to the repulsive forces inside the drop which exceed the surface tension. The mobile phase transforms into the gas phase experiencing this repetitive process. While protonated ions are detected under positive mode, negative mode detects deprotonated ions (Lundanes et al. 2014).

### 2.4.2. ICP-MS

Inductively coupled plasma-mass spectrometry (ICP-MS) is a technique which can be used for multi element analysis of virtually any materials. ICP-MS has the function to precisely determine the concentration of almost all elements in the periodic table including the refractory elements that are often hard to analyze. Likewise, it can obtain concentrations of analyte elements at very low levels (down to $1-10 \mathrm{ng} / \mathrm{L}$ in solution). It is powerful and effective trace analysis apparatus since it runs with a wide linear dynamic work range, high accuracy and precision of measurement, and minimal interference (Taylor 2001).

All atomic spectroscopic techniques need to convert the sample into gas phase atoms and ions as well as atomization of the samples. When the samples are introduced into the atomization source in solution, the equipment makes the analyte species in solution free gas-phase atoms/or elementary ions (West et al. 2014).

Plasma is an electrically neutral gas comprising positive ions and free electrons. It has an enough energy to atomize, ionize and excite almost all element in the periodic table. The inductively coupled plasma (ICP) is the most common ionization method for mass spectrometry. Inert gases are often required to sustain plasma owing to ionization properties and availability in relatively pure form. Argon especially has a useful property leading the minimal chemical reactivity with various analyte species, and less interference with the analytical results (Taylor 2001). When argon ions are formed in plasma, they can absorb sufficient power from external source to keep the fixed temperature at which further ionization maintains the plasma for indefinite period. Thus, the temperature gets achieved as high as 10000 K (West et al. 2014).

Samples can be brought in the ICP with argon flowing through the central quartz tube (Figure 2.6). The nebulizer is often used as sample introduction way. Fine droplets of various sizes can be generated by breaking the liquid with high velocity gas, then these droplets are transferred into the plasma (West et al. 2014).

Figure 2.6: The inductively coupled plasma torch. A: cooling gas flow to outer quartz tube.
B: discharge gas flow. C: flow of carrier gas. D: induction coil. E: force vectors of the magnetic field. F: the plasma torch (discharge).
Retrieved (15.05.2019) from https://en.wikipedia.org/wiki/File:ICP_torch.svg

The ICP-MS system uses the high temperature argon plasma as the atomic ion source as well as quadrupole as a mass analyzer. The formed ions in plasma enter in the mass analyzer which selects according to the mass-to-charge ( $\mathrm{m} / \mathrm{z}$ ) ratio, then sorted ions are detected. Two metal cones usually constitute the interface: the sampler and the skimmer. An attached small orifice (approximately 1 mm ) with each cone lets the ions pass through the optics which leads them into the mass analyzer. ICP-MS spectra can identify and quantify the elements present in the sample. For quantitative analysis, calibration curve based on the ratio of the ion signal for the analyte and internal standard is used to calculate (West et al. 2014).

### 2.5. Quantitation and Quality Assurance

### 2.5.1. Retention time (RT) and relative retention time (RRT)

The RT of a substance is variable, depending on the applied chromatographic system and it can fluctuate between consecutive injections. The representative factors causing the fluctuation are: instability of the flow rate for mobile phase and in column temperature; column degradation; air bubbles in the mobile phase; the difference of the column length. The difficulty of the comparison absolute RT is attributed to these factors. To resolve it, the RRT is a useful method, which the RRT is the ratio between the RT of the analyte and an internal standard (Equation 2-2). Thereby employing the RRT, the fluctuation impact is declined,

## 2. THEORY

since the internal standard is also suffered same impact and the proportion should be the same.

$$
\begin{equation*}
R R T=\frac{R T \text { of the analyte }}{R T \text { of the internal standard }} \tag{2-2}
\end{equation*}
$$

### 2.5.2. Relative response (RR)

The relative response (RR) is the factor to compensate for the gap in the signal intensity of a target analyte. This can be result of the differences during sample preparation (e.g. loss of sample volume) in instrumental response. Therefore, a ratio (called relative response) between the signal intensity of the analyte and the internal standard is employed to compensate the variations (Equation 2-3).

$$
\begin{equation*}
R R=\frac{\text { Response of the analyte }}{\text { Response of the internal standard }} \tag{2-3}
\end{equation*}
$$

### 2.5.3. Ion ratio (IR\%)

The ion ratio is an additional parameter to confirm the target analytes. It is an individual ratio for each chemical in a sample matrix. This value is obtained by calculation: the area of the confirmation ion divided by the area of the quantification ion and multiplied by 100
(Equation 2-4).

$$
\begin{equation*}
I R \%=\frac{\text { Area of the confirmation ion }}{\text { Area of the quantification ion }} \tag{2-4}
\end{equation*}
$$

### 2.5.4. Repeatability and Reproducibility

Repeatability of measurements refers to the variation in repetition measurement made on the same samples under identical conditions. Whereas, Reproducibility refers to the variation in measurement made on the sample conducted under different conditions (Bartlett and Frost 2008). Herein, the reproducibility of the measurements performed between different days are indicated. A measurement can be run with same condition when this variation is less than a pre-determination acceptance criterion. Reproducibility can be obtained by calculating the standard deviation (Equation 2-6) or the relative standard deviation (Equation 2-7). The mean value is given as Equation 2-5.

$$
\begin{equation*}
\bar{x}=\frac{\sum_{i=1}^{n} x_{i}}{n} \tag{2-5}
\end{equation*}
$$

$$
\begin{align*}
& \boldsymbol{S T D}=\sqrt{\frac{\sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2}}{n-1}}  \tag{2-6}\\
& \boldsymbol{R S D} \%=\frac{\boldsymbol{S T D}}{\bar{x}} \times 100 \% \tag{2-7}
\end{align*}
$$

The values such as $x_{1}, x_{2}, \ldots, x_{n}$ are obtained number from the repeated test, $\bar{x}$ is the mean value of the sample, n is the number of samples and $\mathrm{n}-1$ is the degree of freedom. Standard deviation (STD) is employed to measure precision and it provides the amount of variation or dispersion in a data set. Whilst, the relative standard deviation (RSD\%) shows the coefficient of variation and also gives a clearer picture of the data quality than STD (Skoog et al. 2003).

### 2.5.5. Absolute and relative recovery

Recovery is a conception of how an analytical method is effective and used to determine whether analyte detection is affected by the sample preparation process (Meier and Zünd 2005; "Thermo Fisher Scientific" 2019b). The absolute recovery is given as Equation 2-8 and the relative recovery is given as Equation 2-9.

$$
\begin{equation*}
\text { Absolute recovery } \%=\frac{A_{\text {Pre-ext }}}{A_{\text {Post-ext }}} \times 100 \% \tag{2-8}
\end{equation*}
$$

The term of $A_{\text {Pre-ext }}$ is the area of analyte in the pre-extraction spiked sample whereas the term of $A_{\text {Post-ext }}$ is the area of analyte in the post-extraction spiked sample.

$$
\begin{equation*}
\text { Relative recovery } \%=\frac{A_{\text {Pre-ext }} / I S_{\text {Pre-ext }}}{A_{\text {Post-ext }} / I S_{\text {Post-ext }}} \times 100 \tag{2-9}
\end{equation*}
$$

The term of $I S_{\text {Pre-ext }}$ is the area of internal standard in the pre-extraction spiked sample whereas the term of $I S_{\text {Post-ext }}$ is the area of internal standard in the post-extraction spiked sample (B. K. Matuszewski et al. 2003).

The absolute recovery is the "real" recovery however it is regarded containing the higher uncertainty than its relative recovery. The relative recovery is the "corrected" recovery and it compensates effectively for the analyte losses throughout the sample preparation process.

### 2.5.6. Limit of detection and lower level of quantification

The limit of detection (LOD) is the smallest value which is clearly distinguished from a blank. While, the lower level of quantification (LLOQ), called (lowest) limit of quantification, is the smallest value which is can be measured with reasonable accuracy (Harris 2010).

## 2. THEORY

The calculation of LODs and LLOQs can vary within a matrix due to matrix effects and it requires "fit the purpose" of the analytical method (Asimakopoulos 2014). In this study, the LLOQ was used to the lowest concentration detected in calibration (same way with Asimakopoulos 2014) and the LOD is obtained from equation below.

$$
\begin{equation*}
L O D=\frac{L L O Q}{3} \tag{2-10}
\end{equation*}
$$

### 2.5.7. Matrix effect

Evaluating matrix effects is the most important process when developing and LC/MS method. There can be coeluting compounds from matrix which can cause either enhancement or suppression. The ionization efficiency of the analyte may also be affected when the matrix compounds and the analyte are introduced simultaneously to the ion source. Thus, the matrix effect can affect both accuracy of the method and the reproducibility. To deal with matrix effect, the isotope labelled internal standard should be used(Van De Steene and Lambert 2008). Matrix factor (MF) expresses the effect on the analytical signal from the other compounds except the main analyte in the matrix (Silvestro et al. 2013).

$$
\begin{equation*}
M F=\frac{\text { Area }_{\text {Post-ext-spike }}}{\text { Area }} \tag{2-11}
\end{equation*}
$$

The term of Area Post-ext-spike $^{\text {is the area of the post-extraction spiked sample whereas }}$ Area $_{I S}$ is the area of analyte in the standard solution (in solvent matrix) corresponding with same concentration as spiked sample (Silvestro et al. 2013). Furthermore, the matrix effect percentage (ME\%) can be calculated by Equation 2-12 (Asimakopoulos 2014).

$$
\begin{equation*}
M E \%=(M F-\mathbf{1}) \times \mathbf{1 0 0} \% \tag{2-12}
\end{equation*}
$$

### 2.5.8. Internal standard method

The internal standard method consists of a calibration curve in matrix which is conducted for every target analyte plotted the concentration of the spiked analytes against the proportion of the analyte response and the internal standard response in a set of standard solutions.
Validation criteria (i.e. accuracy, reproducibility) can be calculated according to this ratio (Asimakopoulos 2014).
The internal standard is a compound that is very similar however does not correspond with the chemical species of interest in the samples. The signal from the analyte can be compared with the signal from the internal standard and the amount of the analyte present in the sample
can be estimated since a known amount of the internal standard is added to the sample. The internal standard method is very useful when apparatus signal varies from run to run, also the results are not effected by any spilled action during sample preparation (Harris 2010).

### 2.6. Statistics

### 2.6.1. Correlation

Correlation is popular method to measure the relationship between two variables. The correlation efficient (r) can evaluate the strength of correlation. A r-value is assessed as following rule: from 0.90 to 1 is a very high correlation, $0.70-0.89$ is a high correlation, 0.50 0.69 is a moderate correlation, $0.30-0.49$ is a low correlation and $0.00-0.29$ is little (Asuero et al. 2006). While, the p -value of a correlation shows the probability of finding a correlation if there is none. When the p-value is lower, the probability of "false" correlation should be considered as the lower.

### 2.6.2. PCA

PCA is a multivariate method, used to analyze the data table which is represented observations described by several dependent variables. The variables in the data table are inter-correlated in general. The aim of PCA is to: (1) extract the most important data from the table; (2) compress the size of the data set by keeping only this data; (3) simplify the description of the data set; (4) analyze the structure of the variables and observations. Besides, by displaying them as points in maps, PCA can show the similarity of the variables and the observations.

To achieve these aims, PCA calculates new variables known as principal components, obtained as linear combinations of the original variables. The first principal component is needed to have the largest possible variance of variables and then it will explicate the majority of variance in the data table. The second principal is that it computes the largest possible variance under the restraint of being orthogonal to the first principal. The values of these new variables obtained aforementioned process is called factor scores. These factor scores can be construed geometrically as projections of the observations on the principal components.

The data table used for PCA analysis is represented by a $\boldsymbol{I} \times \boldsymbol{J}$ matrix $(\boldsymbol{X})$ containing the observations (I) described by variables $(\boldsymbol{J})$. The rank of the matrix $(\boldsymbol{X})$ is $\boldsymbol{L}(\boldsymbol{L} \leq \boldsymbol{\operatorname { m i n }}\{\boldsymbol{I}, \boldsymbol{J}\})$.

## 2. THEORY

The data is mostly pre-processed prior to analysis, almost always by centering the column of $\boldsymbol{X}$ which is subtracted the mean of each variable from the data thus the mean of each column equals to 0 . The components in PCA are calculated from singular value decomposition (SVD) of the data table (Equation 2-13).

$$
\begin{equation*}
X=P \Delta Q^{T} \tag{2-13}
\end{equation*}
$$

The $\boldsymbol{P}$ is the $\boldsymbol{I} \times \boldsymbol{L}$ matrix of left singular vectors (normalized eigenvectors ${ }^{1}$ of the matrix $\boldsymbol{X} \boldsymbol{X}^{\boldsymbol{T}}$ ), whilst $\boldsymbol{Q}$ is the $\boldsymbol{J} \times \boldsymbol{L}$ matrix of right singular vectors (normalized eigenvectors of the matrix $\boldsymbol{X}^{\boldsymbol{T}} \boldsymbol{X}$ ), and $\Delta$ is the diagonal matrix of singular values (square root of the diagonal matrix of the eigenvalues ${ }^{2}$ of matrix $\boldsymbol{X} \boldsymbol{X}^{\boldsymbol{T}}$ and $\boldsymbol{X}^{\boldsymbol{T}} \boldsymbol{X}$ (as the same)) (Abdi and Williams 2010).

The main principal component (with the highest variance) is the x -axis as new plot while the other component (with the second highest variance) becomes the $y$-axis as it sets the orthogonal to the main component. The "plot" is then rotated; hence the x -axis is horizontal, and the $y$-axis is vertical by means of multiplication the original data due to the eigenvectors which indicate the direction of the principal components. There are two eigenvectors (for each axis) each corresponding to an eigenvalue, the magnitudes of each eigenvalue indicate that the amount of the data's variability is explained by its eigenvector.

PCA is useful technique to identify patterns within a data set, aiming to cluster similar observations. The goal is to visualize and project the data on a two-dimensional coordinate with a minimal loss of information. To accomplish this, the number of variables is declined to a few linear combinations of the data set with linear combination corresponding to a principal component. The loading plot (shown in Appendix G) provides the influential variables for the PCA model and how these variables are correlated. The spots close to each other in the loading plot show similar data profile; the value of one either increases or decreases, it conduce to the same change for proximal components (Asimakopoulos et al. 2016).

[^0]
## 3. MATERIALS and METHODS

### 3.1. Sample collection

A total of 181 food samples were purchased in 7 countries through 2018: Japan, Switzerland, Greece, Germany, Luxemburg, Spain and Norway. Collected snack food stuffs were purchased from local supermarkets and divided into 7 categories according to the country snacks were sold in: 42 samples from Japan, 13 samples from Switzerland, 7 samples from Greece, 23 samples from Germany, 21 samples from Luxemburg, 22 samples from Spain and 53 samples from Norway. Samples were also categorized according to their physical states and the indications such as sold country (Norway/Japan/others), taste (salty/sweet/others), brand, the visual aspect (solid/liquid/others), the type of snacks (grain/chocolate/others) and target age group. The list of all samples is present in Table A. 1 in Appendix A. These samples were stocked in ambient temperature as the supermarket took before treatment.

### 3.2. Method - Organic

### 3.2.1. Chemicals and materials

Analytical standards of MeP, $\operatorname{EtP}(99 \%)$, $\operatorname{PrP}(\geqq 99 \%)$, BuP ( $\geqq 99 \%)$, BezP ( $\geqq 98 \%)$, HeP, 4HB ( $99 \%$ ), 3,4-DHB ( $\geqq 97 \%$ ), Vanillic acid ( $97 \%$ ), OH-EtP ( $97 \%$ ) and TCC ( $99 \%$ ) were purchased from Sigma-Aldrich. Paraben internal standard mix solution containing ${ }^{13} \mathrm{C}_{6}-\mathrm{MeP}$, ${ }^{13} \mathrm{C}_{6}$-EtP, ${ }^{13} \mathrm{C}_{6}-\operatorname{PrP}$ and ${ }^{13} \mathrm{C}_{6}$-BuP was also obtained from Sigma-Aldrich.

Ammonium acetate, ethyl acetate, MeOH were purchased from Sigma-Aldrich. Milli-Q water was purified by Millipore Water distribution system (Merck Millipore, US).

### 3.2.2. Standard solutions

### 3.2.2.1. Internal standard (IS)

For spiking, paraben internal standard mix solution was used. The stock solution was 10 ppm , and to prepare 1 ppm solution, $100 \mu \mathrm{~L}$ of the stock solution was transferred to a glass vial (for LC) by an Eppendorf pipette mixing with $900 \mu \mathrm{~L}$ of MeOH .

### 3.2.2.2. Standard stock solution

Each standard stock solution in this study was 1000 ppm solution. For most of the standard stock solutions, they were prepared by weighting 10 mg of each chemicals in a 10 mL volumetric flask and dissolved with methanol $(\mathrm{MeOH})$. Actual weight of chemicals and concentration of stock solutions were given in Table A.1. From the standard stock solutions, 10 ppm working solutions were prepared. To make the 10 ppm solutions, a calculated amount of standard stock solution was transferred to a 20 mL glass vial by using an Eppendorf pipette prior to diluting up to 10 mL with MeOH . Then, 9 mL of the MeOH were poured by the graduated cylinder, furthermore, the remaining fraction of MeOH was added by an Eppendorf pipette. The calculated amount of standard stock solutions and added MeOH are shown in
Table A.2. Moreover, the 1 ppm solutions prepared by extracting 1 mL of the 10 mL working solution to 20 mL glass vial, then 9 mL of MeOH was added with an Eppendorf pipette.

### 3.2.3. Extraction

Before performing the actual experiment, extraction method development has been carried out. A solid-liquid extraction method was used to extract the parabens, their derivatives and antimicrobial from snack food stuffs. Briefly, snack samples were homogenized (solid samples by a hammer), and approximately 1 g for each sample was weighted and transferred into a 15 mL PP tube. Then, 2 mL of 1 M ammonium acetate was added to PP tube. A known concentration of a mixture of labeled IS ( $10 \mu \mathrm{~L}$ of 1 ppm IS solution prepared in Section 3.3.2.1.) was spiked, vortexed and allowed to equilibrate. To the spiked samples, 6 mL of ethyl acetate was added and shaken in a mechanical shaker (KS501 digital, IKA). After 45 min shaking, the PP tubes were centrifuged at 5000 rpm for 5 min , and the supernatant was transferred into another 15 mL PP tube. This extraction process was repeated with 6 mL of ethyl acetate again, then the second supernatant was transferred into same PP tube stored first supernatant (approximately 12 mL in total). To remove the salts, 1 mL of Milli-Q water was added to PP tube and shaken. After 5 min shaking, it was centrifuged and removed water. The PP tubes were kept in the freezer at $-20^{\circ} \mathrm{C}$ over 24 h to separate the lipid layer. After centrifugation, the lipid phase was removed, and the rest of solution (containing the analytes) was concentrated to near dryness in the TurboVap ${ }^{\circledR}$ Classic LV (Biotage). Further, it was reconstituted with 1 mL of methanol, and transferred into vials for UHPLC analysis.

### 3.2.4. LC-MS/MS

The section of the chromatographic separation was performed using an Acquity UHPLC Thermo system with a column manager, a flow thorough needle manager and binary solvent manager (Waters, Milford, USA). The tandem mass spectrometric system was a Xevo TQ-S (triple quadrupole mass analyzer) with ZSpray ESI (Waters, Milford, USA). The LC column used was Kinetex C18 column ( $2.1 \mathrm{~mm} \times 50 \mathrm{~mm}, 1.3 \mathrm{~mm}$; Phenomenex Inc., Torrance, CA, U.S.) connected to a SecurityGuard ULTRA C18 guard column ( $2.1 \mathrm{~mm} \times$ sub- 2 mm , coreshell column; Phenomenex Inc.). Determinations of the mass spectrometry parameters were carried out by direct infusion and the IntelliStart software (Waters, Milford, USA) (Appendix D). The parent and fragment ions of each target chemicals are shown in Table 3.1.

Table 3.1: Analyte specific MS/MS parameters

| Component | Quantification transition <br> $\left(\mathrm{CE}^{\mathrm{a}}[\mathrm{eV}]\right)$ | Confirmation transition <br> $\left(\mathrm{CE}^{\mathrm{a}}[\mathrm{eV}]\right)$ | $\mathrm{CV}^{\mathrm{b}}(\mathrm{V})$ |
| :---: | :---: | :---: | :---: |
| MeP | $151>92(20)$ | $136(14)$ | 36 |
| EtP | $165>92(20)$ | $137(14)$ | 38 |
| PrP | $179>92(20)$ | $136(16)$ | 28 |
| BuP | $193>92(24)$ | $137(14)$ | 46 |
| BezP | $227>92(22)$ | $136(14)$ | 14 |
| HeP | $235>92(24)$ | $136(20)$ | 20 |
| $4-\mathrm{HB}$ | $137>93(14)$ | - | 30 |
| $3,4-\mathrm{DHB}$ | $153>109(14)$ | - | 30 |
| Vanillic acid | $167>152(20)$ | $108(18)$ | 20 |
| OH-EtP | $181>108(22)$ | $153(14)$ | 18 |
| TCC | $313>160(12)$ | $126(24)$ | 8 |

a: Collision energy $\quad \mathrm{b}$ : Cone voltage

Chromatographic separation was performed by Kinetex ${ }^{\circledR}$ C18 column. Chromatographic analyses were carried out using a gradient elution program with water (acidified with $0.1 \%$ $\mathrm{v} / \mathrm{v}$ formic acid) and methanol as binary mobile phase mixture at a flow rate of $200 \mu \mathrm{~L} / \mathrm{min}$. The gradient elution started with $1 \%(\mathrm{v} / \mathrm{v})$ water and increased linearly to $75 \%$ water in 0.4 min . Then, it increased again to $95 \%$ water for $0.4 \mathrm{~min}(t o t a l ~ 0.8 \mathrm{~min})$ and it was held for 1.7 $\min$ (until 2.5 min ). After holding, it started to increase again up to $99 \%$ for 0.05 min , and then kept $99 \%$ for 0.75 min (until 3.3 min ). The gradient elution reverted to $1 \%$ at 3.5 min
and re-equilibrated for 0.5 min (totally 4 min ). The electrospray ionization voltage was applied at +1.8 kV . The collision gas flow rate was set at $0.15 \mathrm{~mL} / \mathrm{min}$. The source temperature was set at $150^{\circ} \mathrm{C}$ and the desolvation gas temperature was set at $350^{\circ} \mathrm{C}$. The injection volume was $3 \mu \mathrm{~L}$. Data were acquired with the MassLynx and TargetLynx software packages (version 4.1 SCN871, Waters, Milford, USA). Data treatment was carried out with Excel (Microsoft Office, 2019).

### 3.3. Method - Inorganic

### 3.3.1. Sample preparation

Pre-treatment process for 181 samples was carried out before ICP-MS analysis.
All samples were weighted approximately $400-500 \mathrm{mg}$ and transferred to PTFE-Teflon vials $(18 \mathrm{~mL})$. Then, 8 mL of nitric acid $\mathrm{HNO}_{3}$ (UltraPure grade, distilled with Milestone SubPur, $50 \% \mathrm{v} / \mathrm{v}$ ) was added to each sample. After that, samples were put on a high-pressure microwave system (Milestone UltraClave, EMLS, Leutkirch, Germany) and carried out according to a temperature profile which increases gradually from ambient temperature up to $245{ }^{\circ} \mathrm{C}$ within 1 hour. Besides, approximately 1 hour was taken to cool temperature down to initial temperature (Table 3.2). After cooling step, the digested samples were diluted with Milli-Q water up to roughly 90 mL in polypropylene vials to accomplish a final $\mathrm{HNO}_{3}$ concentration $(0.6 \mathrm{M})$. For the certified reference sample, cigarette leaf powder was weighted about 270 mg and transferred to PTFE-Teflon vials $(18 \mathrm{~mL})$ mixed with 8 mL of $\mathrm{HNO}_{3}(50 \%$ $\mathrm{v} / \mathrm{v}$ ) prior to Ultraclave process. After decomposition, it was diluted to approximately 90 mL with Milli-Q water and transferred to polypropylene vial.

Table 3.2: Steps in Ultraclave decomposition

| Step | Time (min) | Temp $1\left({ }^{\circ} \mathrm{C}\right)$ | Temp 2 $\left({ }^{\circ} \mathrm{C}\right)$ | Press (bar) | Energy (Watt) |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 5 | 50 | 60 | 160 | 1000 |
| 2 | 10 | 50 | 60 | 160 | 1000 |
| 3 | 10 | 100 | 60 | 160 | 1000 |
| 4 | 8 | 110 | 60 | 160 | 1000 |
| 5 | 15 | 190 | 60 | 160 | 1000 |
| 6 | 5 | 210 | 60 | 160 | 1000 |
| 7 | 15 | 245 | 60 | 160 | 1000 |
| 8 | 10 | 245 | 60 | 160 | 1000 |

### 3.3.2. ICP-MS

High resolution inductivity coupled plasma mass spectrometer (HR-ICP-MS) analyses were carried out with a Thermo Finnigan model Element 2 instrument (Bremen, Germany). 1350W as the radio frequency power was set. The samples were automatically introduced by the combination with equipped autosampler SC2 DX (with ULPA filter dust cover) and PrepFAST injection analysis system (ESI, Elemental Scientific, Inc. Omaha, NE), with total flow of $200 \mu \mathrm{~L} / \mathrm{min}$. The apparatus was installed nebulizer (PFA-ST), spray chamber (PFA Barrel 35 mm ), demountable torch, quarts standard injector and Aluminum type X-skimmer. By adding the methane gas to the sample gas, the sensitivity of Se and As is increased as oxide is lower level. Appendix F is showing more details about this instrumentation.

Certified calibration solution can verify the accuracy of the ICP-MS instrument. PS-70 and PS-ClBrI were employed for this study as calibration solution (CS) and each of them was prepared two types which were delivered by ESI from independent producers. The solutions from the one producer was used as a CS while the other from the other producer was used as quality solution (QS). To cover the all elements, both of PS-70 and PS-ClBrI were employed since PS-70 is the primary solution containing 70 elements and PS-ClBrI contains chlorine, bromine and iodine which cannot be mixed into PS-70 due to the matrix of HCl . The precision was obtained from RSD\% values which are calculated from three consecutive scans of each sample. The quantification limits ( QL ) were considered by taking the concentration giving approximately $25 \%$ of RSD, uncorrected of baseline whilst the detection limits (DL) was calculated from QL, corrected of baseline and total measurement uncertainly (MU). The total MU is obtained by Equation 3-1.

$$
\begin{equation*}
M U=\sqrt{D L^{2}+D L^{\prime 2}} \tag{3-1}
\end{equation*}
$$

$D L^{\prime 2}$ is the $D L$ with baseline correction.

### 3.4. Data treatment

Statistical analysis and correlations were performed by SPSS Statistics (IBM, version 25) and principal component analysis (PCA) was carried out by the statistical software R.

## 4. RESULTS and DISCUSSION

### 4.1. Quality assurance and method validation

### 4.1.1. Organic analysis

The precision of the tandem LC-MS/MS method is given in Table 4.1. All of the ion ratios (IR\%) satisfy the criteria of tolerance announced by Commission Decision 2002/657/EC (European Commission 2002).

Table 4.1: Ion ratios $(I R \%)$, Retention times $(R T)$ and Relative retention times ( $R R T$ ) (RSD\%, $\mathrm{N}=3$ highest calibration points)

|  | $I R \%$ | $R T$ | $R R T$ |
| :--- | :---: | :---: | :---: |
| MeP | $59.3(5.07)$ | $1.61(0.29)$ | $1.00(0.29)$ |
| EtP | $97.2(1.62)$ | $1.80(0.00)$ | $1.00(0.00)$ |
| PrP | $18.3(1.53)$ | $1.98(0.24)$ | $1.00(0.24)$ |
| BuP | $38.8(2.26)$ | $2.16(0.22)$ | $1.00(0.00)$ |
| BezP | $78.1(0.12)$ | $2.15(0.22)$ | $0.995(0.001)$ |
| HeP | $23.1(0.80)$ | $2.62(0.00)$ | $1.21(0.22)$ |
| 4-HB | - | $1.21(0.39)$ | $0.75(0.39)$ |
| 3,4-DHB | - | $0.99(0.47)$ | $0.62(0.47)$ |
| Vanillic acid | $53.8(9.00)$ | $1.27(0.37)$ | $0.79(0.37)$ |
| OH-EtP | $72.8(1.49)$ | $1.61(0.00)$ | $1.006(0.00)$ |
| TCC | $7.79(2.67)$ | $2.59(0.18)$ | $1.20(0.18)$ |

The recoveries for this method are shown in Table 4.2. The absolute recoveries in the majority of target analyte are more than 70 \%. Regarding the parabens (MeP, EtP, PrP, BuP, BezP and HeP ), the recoveries of the target analyte are similar to previous studies (Alshana et al. 2015; Jain et al. 2013; Liao et al. 2013b, 2013a; Molognoni et al. 2018; Prapainop et al. 2019). This is the first work for the determination of $4-\mathrm{HB}, 3,4-\mathrm{DHB}$, vanillic acid, OH-EtP and TCC especially in the snacks. The recoveries of $4-\mathrm{HB}$ and $3,4-\mathrm{DHB}$ at $20 \mathrm{ng} / \mathrm{mL}$ were quite high value compared to other concentration. It might get produced during preparation process. For OH-EtP and TCC, there showed good recoveries with $81.0 \%$ and $79.5 \%$ for absolute and $99.5 \%$ and $112.3 \%$ for relative in total value respectively. However, the recoveries of 4-HB, 3,4-DHB and vanillic acid in total value were low values thus these compounds were semiquantified.

## 4. RESULTS and DISCUSSION

Table 4.2: Recoveries $\% ~(R S D \%, N=4 ; 10[\mathrm{ng} / \mathrm{mL}], \mathrm{N}=3 ; 20[\mathrm{ng} / \mathrm{mL}], \mathrm{N}=4 ; 25[\mathrm{ng} / \mathrm{mL}], \mathrm{N}=4 ; 50[\mathrm{ng} / \mathrm{mL}])$ of target analytes.

### 4.1.2. Inorganic analysis

Almost all elements in snack food stuffs used for discussion (Table 4.10) have been detected above the quantification limits. The detection limit for all elements are given in Table C. $\mathbf{1}$ in Appendix C. The process of calculations for detection limits for ICP-MS is written in

Section 3.3.2. Each individual sample was analyzed for 3 times for seeing precision.
Furthermore, some samples were also used for repeating test in order to confirm its validity. 10 parallels have been analyzed as replication as well. Accuracies (analyzed/certified values) were $\pm 20 \%$ maximum which was verified against certified reference material.

## 4. RESULTS and DISCUSSION

### 4.2. Concentration of parabens and elements in snack samples

### 4.2.1. Parabens

Figure 4.1 shows the overall proportion of parabens, parabens derivatives and all analytes in the snack food samples $(\mathrm{n}=181)$.

Figure 4.1: Distribution profiles of the amount of target analytes leached from snack food stuffs (based on median concentrations)

Among the parabens, EtP and MeP are the highest and the second highest percentage respectively, and $4-\mathrm{HB}$ and $3,4-\mathrm{DHB}$ account $97 \%$ of parabens derivatives. By contrast, PrP, BezP and HeP are very low ratio. Considering the all target analytes, 4-HB, 3,4-DHB and vanillic acid are abundant and occupies $96 \%$. Parabens are significantly poor rate compared to the parabens derivatives. This indicates that parabens derivatives are formed by chemical reactions of parents parabens through the manufacture or storage processes, as mentioned by Asimakopoulos et al. (2016). Alkyl protocatechuates that were found in food samples were potentially formed from parent parabens by photo-oxidation. The process of light-induced hydroxylation of MeP transforming to $\mathrm{OH}-\mathrm{MeP}$ has been studied, then the relationship between EtP and OH-EtP is also considered as following similar way (Okamoto et al. 2008). The reaction mechanism of $4-\mathrm{HB}$ and $3,4-\mathrm{DHB}$ from parabens in food, however, is still

## 4. RESULTS and DISCUSSION

insufficient, while the transformation process of $4-\mathrm{HB}$ and $3,4-\mathrm{DHB}$ from paraben in organism has been proved in human and animal studies (Aubert et al. 2012; Liu et al. n.d.; Ste-Marie et al. 1999; Wang and Kannan 2013). Vanillic acid has been reported that it is a phenolic derivative of edible plants and fruit, as well as an intermediate of vanillin which is common non-toxic food additive and confers the odor and vanilla taste (Noubigh and Abderrabba 2016; Sayavongsa et al. 2007). The ingredients of plenty of samples used this study are plant-derived such as grain, chocolate, fruit and vegetable (see Table 4.8, 4.9). This, therefore, makes it reasonable to presume that vanillic acid accounts large ratio of the distribution profiles.

The concentrations of the food samples from different countries are shown in Table 4.6 and Table 4.7. The highest median concentration of total target analyte is the snacks sold in Switzerland ( $660 \mathrm{ng} / \mathrm{g}$ ) and the lowest one is the snacks bought in Spain $(93.4 \mathrm{ng} / \mathrm{g})$. It is almost seven times difference. Furthermore, the samples from Switzerland and Spain are also the highest and lowest concentrations of parabens ( $\Sigma$ Parabens) and parabens derivatives ( $\Sigma$ Parabens derivatives). Focusing on individual analytes, maximum concentration of MeP in Japan and Luxembourg and PrP in Luxembourg were 292, 5109 and $1198 \mathrm{ng} / \mathrm{g}$ respectively, which were extremely higher concentration than what of median concentration ( $0.86,1.38$ and $0.17 \mathrm{ng} / \mathrm{g}$ respectively). This result was found only at MeP and PrP among parabens, hence these parabens were considered having substantially wide variability. Besides, 4-HB and vanillic acid are always high concentration, while HeP and TCC are very low concentration in all samples. Vanillic acid in Japanese samples is remarkably high concentration ( $298 \mathrm{ng} / \mathrm{g}$ ) and it is nine times larger than Spanish samples which are the lowest concentration ( $32.2 \mathrm{ng} / \mathrm{g}$ ). TCC is not often used for the food stuffs according to the Table 4.6 and 4.7, the number of detected samples are below half samples with very low concentration.

The distribution of the individual parabens (Figure 4.2.) indicates that MeP and EtP are the major components in the all countries except Luxembourg where $\operatorname{PrP}$ is the second major components instead of EtP. On the other hand, HeP is rarely used as preservative for snack food stuffs, as well as there are very low number of samples detected HeP in Table 4.6 and 4.7 compared to the other parabens. HeP was also seldom used for food items from China, as frequencies were nearly $0 \%$ (Liao et al. 2013a). PrP, BuP and BezP are still detected in many samples although the composition rates are low (below $4.0 \%$ except two points). For the partition of parabens derivatives (Figure 4.3), 4-HB and 3,4-DHB are the major components, further, 3,4-DHB accounts for over the greater part in all countries. While, OH-EtP is not almost contained in the food stuffs from all countries although it was detected over the half of samples (Table 4.6 and 4.7).

## 4. RESULTS and DISCUSSION

Table 4.8 and 4.9 provide the concentrations of the target analytes in the food stuffs classified into 8 categories depending on the characteristics. Seafood is $1225 \mathrm{ng} / \mathrm{g}$ (median value) in total analytes, which is the highest concentration among 8 categories. On the contrary, Sugar results the lowest concentration ( $15.6 \mathrm{ng} / \mathrm{g}$ ) though it consists of just 2 samples. The second lowest concentration is $38.1 \mathrm{ng} / \mathrm{g}$ found in Gelatin, which is approximately 30 times less than Seafood. 4 analytes were detected in Sugar products, and the Vegetable products were detected 6 out of 11 analytes although almost all analytes were detected in the other categorized products except HeP. It indicates that Sugar products are made up with mainly sugar with very low additives, and Vegetable products is apparently reluctant to be added other additives. Fruit showed the highest concentration of total of paraben derivatives. It is presumed that Fruit has originally contained those, and it may have enhancement for proceeding the metabolite reaction stated in previous study. Chocolate contained relatively large amounts of parabens ( $13.7 \mathrm{ng} / \mathrm{g}$ ). It seems to have been added many preservatives as one of ingredients is dairy product likely to be spoiled; the combining the parabens is expected to demonstrate better antimicrobial property than only one use. The TCC was detected over half samples in Gelatin, Seafood and Meat. According this result, it is considered that these products need to prevent microbial growth.

Figure 4.4 and 4.5 show the distribution of parabens and parabens derivatives against $\Sigma$ Parabens and $\Sigma$ Parabens derivatives respectively. In every category except sugar, MeP and EtP are the main compositions. This is also reported in Liao et al. (2013a, 2013b) that MeP, EtP and PrP are the predominant analogs found in food samples. The composition pattern of parabens in this study is quite similar to what was reported for human blood and urine ( MeP $\gg \operatorname{PrP}>\mathrm{EtP})($ Calafat et al. 2010; Frederiksen et al. 2011), however, it is similar with food analysis (Liao et al. 2013a, 2013b). BezP occupies 24.6 \%, $8.9 \%$ and $3.5 \%$ in Vegetable, Meat and Grain respectively, which are especially higher percentage than other categories (almost $0 \%$ ). Likewise, $\operatorname{PrP}$ and BuP are higher percentage at 2 categories, then other kinds of snacks scarcely comprise them. To my far knowledge, this is first study to analyze parabens derivatives in food stuffs but due to aforementioned reason, 4-HB and 3,4-DHB are really high distribution.

## 4. RESULTS and DISCUSSION

### 4.2.2. Elements

The concentrations of elements detected in the snack food samples are given in Table 4.10.6 The macromineral elements, which are potassium, sodium, phosphorous, sulfur, magnesium and calcium, are the highest six elements in concentrations (median) and detected almost all samples. Then, essential trace elements for human health and beneficial bioactive trace elements are following the macromineral elements. According to Table 4.10, the elements needed for keeping human health are contained in the commercial products even though the snack food stuffs (Berdanier et al. 2013; Michigan Medicine 2018). Table 4.10 also supports that the macromineral elements were contained at larger levels of concentration in food stuffs than trace elements (Chevallier et al. 2015; Moreda-Piñeiro et al. 2018). Majority of elements shown the table were detected at high detection rate, however, there were some elements detected relatively low rate, such as $\mathrm{Ga}(16.6 \%)$, $\mathrm{Ge}(16.6 \%)$, Sc ( $14.4 \%$ ), and in particular Ir no-detected ( $0 \%$ ).

Table 4.11 provides the differences between countries at the concentrations of selected elements. Full table of it can be found in Table C. 2 in Appendix C. Many kinds of elements were contained in Japanese and Norwegian snacks at the lowest concentrations although Japanese snacks had the highest level ( $5792860 \mathrm{ng} / \mathrm{g}$ at Na ) in the Table 4.11. It is considered that lots of salt are contained in the snacks. The principal difference of snacks between Japan and European countries is use of soy sauce as condiment, since rise crackers collected in Japan often contained soy sauce however European snacks did not it. The amount of soy sauce is one of the factor to show this result (Mandl 2017). Large number of snacks which contained the highest level at each element were from Switzerland, following Germany and Greece. Whereas, the products from Luxembourg and Spain showed moderate concentrations at each element. The element having the largest gap between countries is Na, Japanese snacks are approximately 12 times larger than the lowest concentration ( $469317 \mathrm{ng} / \mathrm{g}$, Norway) though the other gaps are less than about $2 \sim 6$ times. Any other obvious differences apparently are not shown, as many collected samples are produced in international company and those are often imported and exported. Thus, there is not clear border which divides countries based on their elemental contents.

## 4. RESULTS and DISCUSSION

*: detection rate [\%]

## 4. RESULTS and DISCUSSION

The differences between characteristics are given in Table 4.12. Full table of concentrations of all elements detected in the snack food stuffs can be found in Table C. 3 in Appendix C.

Among macrominerals, meat products had the highest concentrations at $\mathrm{K}, \mathrm{P}$ and S , which elements are mainly from meats stated in Michigan Medicine (2018). Meat, Chocolate and Grain were high concentration at K , since these categories are known as the main sources of it. Likewise, the categories containing the high concentrations of other macrominerals are also main sources of those elements. According to previous study, the amount of potassium in chocolate was $167-170 \mathrm{mg} / 100 \mathrm{~g}$, which was lower than what of this study $(362 \mathrm{mg} / 100 \mathrm{~g}$, converted unit), oppositely grains were approximately $500 \mathrm{mg} / 100 \mathrm{~g}$ in previous study, which was higher than what of this study ( $213 \mathrm{mg} / 100 \mathrm{~g}$, converted unit) (The Office of Disease Prevention and Health Promotion 2015). The largest gap between the highest and lowest is present at Na, the highest is $23597279 \mathrm{ng} / \mathrm{g}$ at Seafood and the lowest is $39336 \mathrm{ng} / \mathrm{g}$ at Fruit. Seafood has approximately 600 times higher concentration than what Fruit has. All fruit flavor snacks are not salty, hence the fact that Fruit contains few Na is consider as appropriate result. For trace elements, the categories having the highest concentrations also followed previous study. $\mathrm{Fe}, \mathrm{Zn}$ and Mn , for instance, were rich in Chocolate, Meat and Grain respectively. Fe is often contained in the cereals (e.g. cacao), meats have lots of Zn and plant foods include plenty of Mn (Berdanier et al. 2013; Michigan Medicine 2018).

Almost all elements were detected in each category, but some elements were detected in very low frequency. $\mathrm{Mo}, \mathrm{Cr}, \mathrm{Se}, \mathrm{Co}$ and Cd in Gelatin were less than $50 \%$ detection rate. Moreover, some of these elements were also relatively low percentage (less than $80 \%$ ) compared to Macrominerals at Grain and Fruit. In particular, Si demonstrated unique detection rate. Although Si showed relatively high concentrations among elements, the detection rate was especially low rate in comparison with elements presented high concentration. Furthermore, Vegetable and Sugar did not contained Si. Some kinds of vegetables did not also detect in the previous study (Powell et al. 2005) though other samples analyzed in its article contained even few amount. For Sugar products, it provided poor concentrations of almost all elements except Mg which was the highest among the 8 categories. Many elements were not detected in Sugar; it was scarcely added any other additives, and this also supports discussion at Section 4.2.1 about Sugar.

*: detection rate [\%]

[^3]
### 4.3. PCA

The PCA analysis is powerful tool to show a "fingerprint" of the sample matrices. The PCA makes the samples grouped or separated based on the variation in the samples. The samples become the groups together under same relationships between the components analyzed. It is possible to use it to analyze an unknown sample matrix for the same components, as well as distinguish the matrix depending on the placement in the PCA score plot. There are figures edited to capture the features in this section and the original figures are presented in

## Appendix G.

It can be found the relationships with chemicals in Figure 4.6. Red line went through among MeP, EtP, BuP and OH-EtP, likewise blue line went through among BezP, 4-HB and 3,4DHB. It was considered that these elements were very similar property each other; the elements nearly red line were parabens with alkyl chain and OH-EtP was derivative of EtP, the elements nearly blue line were parabens derivatives and BezP having additional aromatic ring unlike other parabens. Besides, PrP was present between red and blue line, hence it would have similar property. Apart from these elements, vanillic acid and triclocarban were present absolutely different area. It is presumed to appropriate result since vanillic acid is slightly different structure from parabens and triclocarban is antimicrobial substance.

## 4. RESULTS and DISCUSSION

Figure 4.6: The relationship between target analytes

## 4. RESULTS and DISCUSSION

Figure 4.7 provides the PCA analysis result based on characteristics. It was possible to separate Meat, Vegetable, Seafood, Chocolate and Gelatin but it was not completely. Grain spread widely overlapping with 5 categories, and Fruit also contained all Vegetable; it is natural to consider that Vegetable has relationship with Fruit as these are same plant food. Furthermore, it can be seen that Gelatin covered over Sugar; Gelatin products are often sweet snacks (e.g. jelly) so the points were present similar area, however Chocolate as absolute sweet snack was in completely different area.

There were clear separations between forms in Figure 4.8. Gel, Liquid and Gum were grouped completely, however Solid was widespread and over Gel group. Generally, Gel is defined as mostly liquid, but it often behaves like solid. Based on this, Gel group was considered that they were present really close to Solid area. Although the property of Gum is assumed to nearly solid than what of Gel, it was exhibited far from Solid. For elements distribution, the majority of elements were present near Solid and partly Gel; Liquid and Gum were apart. Therefore, Solid products tend to contain various kind of elements than Liquid and Gum products.

For the Figure 4.9, Sour and Neutral taste were clearly separated, however Sweet and Salty taste covered Sour and Neutral taste. Ideally, Sweet\&Salty and Sweet\&Sour should be in the area overlapped with Sweet-Salty and Sweet-Sour respectively, but these were only in the Sweet taste area. Regarding element, Na, which constructs salt, was in the area of Salty. This is strong evidence that the taste and element would have relationship obviously.

Three age groups (All, Child and Infant) were set to find relationships in Figure 4.10. There were not exactly separations between each age, but it could be found that rough age groups. The snacks for Infant and Child were grouped with subtly overlapping; it is reasonable result that some products did not displayed clearly for suitable age. As far as seeing Figure 4.10, the snacks for All were near in the various kind of elements and organic target analytes, while the snacks for Child were relatively far from elements and analytes, then for Infant was present apart from them. Hence, it is thought that the snacks suitable for infant were scarcely added any additives which are often used for food products.

Unlike above PCA results, it is difficult to make groups for country in Figure 4.11. Every mark was dispersed on the figure; it is due to the active international trade. The samples collected for this study were classified as where it was purchased not where it was produced. Therefore, samples could not be grouped depending on the countries.

## 4. RESULTS and DISCUSSION

Figure 4.12 showed correlation between elements and target analytes. Full of the correlation is given in Table G. 6 in Appendix G. There were noticeable correlations with organic analytes; it was Na . It can be seen negative relationships with $\mathrm{Na} \& E t P$ and $\mathrm{Na} \& \mathrm{OH}-E t P$. It means that as higher concentration of $\mathrm{Na}, \mathrm{EtP} / \mathrm{OH}-E t P$ would be lower concentration. 3,4DHB had lots of positive correlations between elements and also parabens which are parent chemicals of 3,4-DHB. Vanillic acid and 4-HB apparently did not have relationships, and the other organic analytes had slight correlations with elements.

Figure 4.12: A part of correlations between elements and organic analytes

## 5. CONCLUSIONS

## 5. CONCLUSIONS

The extraction method employed in this study, solid-liquid extraction (SLE), worked well for separating the organic target analytes from snack food samples, with good reproducibility and high recoveries for parabens. Parabens derivatives, 4-HB and 3,4-DHB, and vanillic acid, demonstrated very low recoveries, interpreting more appropriate to take semi-quantification for these analytes. Another parabens derivative, OH-EtP, and triclocarban as antimicrobial, indicated high recoveries as well. All the organic target analytes were detected in the snack food stuffs though only HeP was extremely low detection rate through the whole. HeP was also hardly ever detected in previous study. Hence, it can be said that the employed extraction method is strong way to derive analyte from snacks.

The parabens derivatives, particularly 4-HB and 3,4-DHB, generally showed higher concentration than parabens, their parent chemicals. This is a reasonable result because 4-HB and 3,4-DHB were the metabolites of parabens; it is considered that the derivatives were resulted of the chemical reaction while storage period from production process. However, the actual process/reaction of it during storage period in snack food stuffs was not investigated in this study. For parabens, the noteworthy result is about HeP as stated above. Not only low detection rate, but it showed very low concentration in spite of having long alkyl chain which has stronger antimicrobial property than detected organic analytes having shorter alkyl chain. The popular parabens often used for snacks were MeP and EtP, which occupied approximately $80 \%$ of all parabens added to snacks. The simplest parabens demonstrating relatively weaker antimicrobial property are generally selected for snacks aiming to preserve it for long period. Although HeP expected to be capable for antimicrobial activity were not often employed for snacks, the parabens with short alkyl chain were usually used for snacks with combination of various parabens expected more antimicrobial property than single used.

No clear trends were found when categorizing the samples by country. It is presumed that every snack/ingredient are often imported/exported so it is regarded as no border for stuffs. While, there were some analytes which were not detected in a specific category. Sugar products, which is one of those characteristics, contained absolutely low concentrations of target analytes, as well as the number of detected analytes were 4 out of 11 analytes. This is independent result than any other analytes.

For elemental analysis, the 6 macromineral elements had much higher concentrations than the other elements. The essential elements for keeping human health were also contained with

## 5. CONCLUSIONS

high concentrations in even snack food stuffs, which are usually known as discretionary food (unessential for life). Almost all target elements were detected with high percentage, whilst some elements were determined with low percentage, further Ir was not detected. Japanese samples often contained Na which demonstrates the existence of salt. It is considered that there is the difference of ingredients between European country and Japan (possibly Asia). The categories having high concentration of macromineral elements and trace elements were almost same with the source of those stated in previous studies.

Regarding PCA analysis, it was possible to make different snack samples grouped depending on the characteristic, form, taste and suitable age. However, it was impossible to separate them as country, which might be aforementioned reason. Besides, target organic analytes were also shown as similar structure/property in the way on the same line. Vanillic acid and triclocarban were located in different areas than those element on the line. Every PCA results demonstrating the group have seemingly appropriate reason, however there are large differences between a number of collected samples where were purchased in or what were characteristics. The relationships were found between organic and inorganic analytes; it can be useful to know the how amount of organic analyte contained when seeing the nutritional information on the package of products.

In conclusion, this is the first study that successfully determined 4-HB, 3,4-DHB, vanillic acid, OH-EtP and TCC in snack food stuffs. The concentrations of parabens often used for preservation of snack food stuffs were generally much lower than those of paraben derivatives since it would be attributed to transformation process from parabens. HeP having long alkyl chain was scarcely used as food additive contrary to strong antimicrobial activity. MeP and PrP were present the wide variability. Many elements were detected, and the result implied the difference of ingredients depending on area, however snacks contained essential elements at higher concentration for human health.

In the present study, a very wide variety of snacks were analyzed, with a low number of each type of snack. Future studies should focus on specific types of snacks collecting higher number of samples. The study emphasizes the value of simultaneous analysis of both organic and inorganic analytes, to evaluate results from a multidirectional view, to study differences by countries and by snack characteristics, and to possibly comment upon positive or negative health effects.

## Appendix D

MS/MS Fragmentation under Negative Ionization Mode

## MeP - Methyl paraben

| Compound | Formula/Mass |  | Parent <br> $\mathbf{m} / \mathbf{z}$ | Cone <br> Voltage <br> $(V)$ | Daughters | Collision <br> Energy <br> $(\mathbf{e V})$ | Ion <br> Mode |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| MeP | C8H8O3 | 1 | 151.02 | 36 | 92.05 | 20 | ES- |
|  |  | 2 | 151.02 | 36 | 135.98 | 14 | ES- |
|  |  | 3 | 151.02 | 36 | 119.02 | 16 | ES- |

EtP - Ethyl paraben

Ethyl-4-hydroxybenzoate

| Compound | Formula/Mass | Parent <br> $\mathbf{m} / \mathbf{z}$ | Cone <br> Voltage <br> (V) | Daughters | Collision <br> Energy <br> $(\mathbf{e V})$ | Ion <br> Mode |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| EtP | C9H10O3 | 1 | 165.03 | 42 | 92.13 | 20 | ES- |
|  |  | 2 | 165.03 | 42 | 136.92 | 14 | ES- |
|  |  | 3 | 165.03 | 42 | 74.91 | 36 | ES- |

Propyl-4-hydroxybenzoate

| Compound | Formula/Mass | Parent <br> $\mathbf{m} / \mathbf{z}$ | Cone <br> Voltage <br> (V) | Daughters | Collision <br> Energy <br> (eV) | Ion <br> Mode |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| PrP | C10H12O3 | 1 | 179.05 | 28 | 92.12 | 20 | ES- |
|  |  | 2 | 179.05 | 28 | 136.24 | 16 | ES- |
|  |  | 3 | 179.05 | 28 | 57.03 | 30 | ES- |

BuP - Butyl paraben

Butyl-4-hydroxybenzoate

| Compound | Formula/Mass | Parent <br> $\mathbf{m} / \mathbf{z}$ | Cone <br> Voltage <br> (V) | Daughters | Collision <br> Energy <br> $(\mathbf{e V})$ | Ion <br> Mode |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| BuP | C11H14O3 | 1 | 193.06 | 46 | 92.11 | 24 | ES- |
|  |  | 2 | 193.06 | 46 | 136.76 | 14 | ES- |
|  |  | 3 | 193.06 | 46 | 70.99 | 32 | ES- |

BezP - Benzyl paraben

| Compound | Formula/Mass |  | Parent <br> $\mathbf{m} / \mathbf{z}$ | Cone <br> Voltage <br> (V) | Daughters | Collision <br> Energy <br> (eV) | Ion <br> Mode |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| BezP | C14H12O3 | 1 | 227.05 | 14 | 91.99 | 22 | ES- |
|  |  | 2 | 227.05 | 14 | 135.99 | 14 | ES- |
|  |  | 3 | 227.05 | 14 | 183.12 | 12 | ES- |

## HeP - Heptyl paraben

Heptyl-4-hydroxybenzoate
\(\left.$$
\begin{array}{|l|l|l|l|l|l|l|l|}\hline \text { Compound } & \text { Formula/Mass } & \text { Parent } \\
\mathbf{m / z}\end{array}
$$ \begin{array}{l}Cone <br>
Voltage <br>

(V)\end{array}\right)\) Daughters $\left.$| Collision |
| :--- |
| Energy |
| (eV) |$\quad$| Ion |
| :--- |
| Mode | \right\rvert\,

4-HB - 4-Hydroxybenzoic acid

4-Hydroxybenzoic acid

| Compound | Formula/Mass |  | Parent m/z | Cone <br> Voltage <br> (V) | Daughters | Collision <br> Energy (eV) | Ion <br> Mode |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 4-HB | C7H6O3 | 1 | 136.94 | 36 | 92.98 | 14 | ES- |

## 3,4-DHB-3,4-dihydroxybenzoic acid

3,4-dihydroxybenzoic acid/Protocatechuic acid

| Compound | Formula/Mass | Parent <br> $\mathbf{m} / \mathbf{z}$ | Cone <br> Voltage <br> (V) | Daughters | Collision <br> Energy <br> $(\mathbf{e V})$ | Ion <br> Mode |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 3,4-DHB | C7H6O4 | 1 | 152.99 | 34 | 108.97 | 14 | ES- |

Vanillic acid-4-hydroxy-3-methoxybenzoic acid

4-hydroxy-3-methoxybenzoic acid

| Compound | Formula/Mass |  | Parent m/z | Cone Voltage (V) | Daughters | Collision <br> Energy <br> (eV) | Ion <br> Mode |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Vanillic acid | C8H8O4 | 1 | $\begin{aligned} & 167.01 \\ & 167.01 \end{aligned}$ | $\begin{aligned} & 20 \\ & 20 \end{aligned}$ | $\begin{aligned} & 151.97 \\ & 107.98 \end{aligned}$ | $\begin{aligned} & 12 \\ & 18 \end{aligned}$ | ES- <br> ES- |

OH-EtP - Ethyl protocatechuic acid

Ethyl 3,4-dihydroxybenzoate
\(\left.$$
\begin{array}{|l|l|l|l|l|l|l|l|}\hline \text { Compound } & \text { Formula/Mass } & \text { Parent } \\
\mathbf{m} / \mathbf{z}\end{array}
$$ \begin{array}{l}Cone <br>
Voltage <br>

(V)\end{array}\right)\) Daughters $\left.$| Collision |
| :--- |
| Energy |
| (eV) |$\quad$| Ion |
| :--- |
| Mode | \right\rvert\,

TCC - Triclocarban

3-(4-Chlorophenyl)-1-(3,4-dichlorophenyl) urea

| Compound | Formula/Mass |  | Parent <br> $\mathbf{m} / \mathbf{z}$ | Cone <br> Voltage <br> $(V)$ | Daughters | Collision <br> Energy <br> $(\mathbf{e V})$ | Ion <br> Mode |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| TCC | C13H9Cl3N2O | 1 | 312.88 | 8 | 159.95 | 12 | ES- |
|  |  | 2 | 312.88 | 8 | 126.42 | 24 | ES- |
|  |  | 3 | 312.88 | 8 | 125.96 | 22 | ES- |

## Appendix E

## Calibration curves

Figure E.1: Absolute calibration curves

Appendix E. Calibration curves

Figure E.2: Absolute calibration curves (continued)

Figure E.3: Relative calibration curve

Figure E.4: Relative calibration curve (continued)

## Appendix F

## ICP-MS parameters

Table F.1: Specifications for ICP-MS, Element 2 from Thermo Scientific

| Instrument | Specification |
| :--- | :--- |
| Autosampler | SC2 DX equipped with a dustcover with ULPA filter |
| Sample injector | prepFAST |
| Nebulizer | PFA-ST with approximately volume range $50-700 \mu \mathrm{~L} / \mathrm{min}$ |
| Spray chamber | Quarts baffled micro cyclonic with dual gas inlet type |
|  | (ESI-ES-3452-111-11) |
| Cooling | PC $^{3 \mathrm{x}}-$ Peltier cooling and heated inlet system |
| Torch | Quarts Demountable with o-rings |
| Injector | Quarts 2.5 mm with o-rings (ES-1024-0250) |
| Sample cone | Aluminum (ES-3000-18032) |
| Skimmer cone | Aluminum type X-skimmer (ES-3000-1805 X) |
| Radio frequency - power | 1350 W |

Table F.2: Gas flow setting for ICP-MS

| Gas type | Flow [L/min] |
| :--- | :--- |
| Cool gas | 15.5 |
| Auxiliary gas | 1.1 |
| Sample gas 1 (nebulizer) | 0.75 |
| Sample gas 2 (T-connection) | 0.55 |
| Additional gas | 0.0004 corresponds to approximately $0.04 \%$ |
|  | $(10 \%$ methane in Argon) in the sample |

## Appendix G

## Principal component analysis (PCA) data

Appendix G. Principal component analysis (PCA) data

Figure G.1: PCA of organic analytes and elements grouped by characteristics

Appendix G. Principal component analysis (PCA) data

Figure G.2: PCA of organic analytes and elements grouped by countries

Appendix G. Principal component analysis (PCA) data

Figure G.3: PCA of organic analytes and elements grouped by forms

Appendix G. Principal component analysis (PCA) data

Figure G.4: PCA of organic analytes and elements grouped by tastes

Appendix G. Principal component analysis (PCA) data

Figure G.5: PCA of organic analytes and elements grouped by suitable ages

Figure G.6: Correlations of concentration of organic analytes and elements used for PCA

[^0]:    ${ }^{1}$ Non-zero vector that changes only by a scalar factor, not in direction, when linear transformation is applied to it
    ${ }_{2}^{2}$ Scale factor corresponding to eigenvector

[^1]:    ${ }^{*}$ : detection rate $[\%](\mathrm{n}=181)$

[^2]:    3 Calculated from the values above detection limit so possibly median would be below detection limit if calculation includes all detected values.

[^3]:    4 Calculated from the values above detection limit so possibly median would be below detection limit if calculation includes all detected values.
