Keywords: causality, retardation, quantum field theory, gauge invariance, radiation processes, quantum uncertainty, classical and quantum interreference

Abstract

In an exact quantum-mechanical framework we show that space-time expectation values of the second-quantized electromagnetic fields in the Coulomb gauge in the presence of a classical conserved source automatically lead to causal and properly retarded h-independent electromagnetic field strengths. The classical h-independent and gauge invariant Maxwell’s equations naturally emerge in terms of quantum-mechanical expectation values and are therefore also consistent with the classical special theory of relativity. The fundamental difference between interference phenomena due to the linear nature of the classical Maxwell theory as considered in, e.g., classical optics, and interference effects of quantum states is clarified. In addition to these issues, the framework outlined also provides for a simple approach to invariance under time-reversal, some spontaneous photon emission and/or absorption processes as well as an approach to Vavilov-Cherenkov radiation. The inherent and necessary quantum uncertainty, limiting a precise space-time knowledge of expectation values of the quantum fields considered, is, finally, recalled.

1. Introduction

The roles of causality and retardation in classical, h-independent, and quantum-mechanical versions of electrodynamics are issues that one encounters in various contexts (for recent discussions see, e.g., [1–14]). In electrodynamics it is natural to introduce gauge-dependent scalar and vector potentials. These potentials do not have to be local in space-time. It can then be a rather delicate issue to verify that gauge-independent observables obey the physical constraint of causality and that they also are properly retarded. Attention to this and related issues are often discussed in a classical framework where one explicitly shows how various choices of gauge give rise to the same electromagnetic field strengths (see, e.g., the excellent discussion in [8]). Even though issues related to causality in physics have been discussed for many years they are still open for investigations and we are facing new insights regarding such fundamental concepts. In a recent investigation [12] the near-, intermediate-, and far-field causal properties of classical electromagnetic fields have, e.g., been discussed in great detail. In terms of experimental and theoretical considerations, locally backward velocities and apparent super-luminal features of electromagnetic fields were demonstrated. Such observations do not challenge our understanding of causality since they describe phenomena that occur behind the light front of electromagnetic signals (see, e.g., [7, 12, 14] and references cited therein).

In the present paper, we investigate the problems mentioned above, in a quantum-mechanical framework. Some aspects of this were, in fact, already considered a long time ago by Fermi [15]. Here we consider, in particular, the finite time and exact time-evolution as dictated by quantum mechanics with second-quantized electromagnetic fields in the presence of arbitrary classical conserved currents.

In terms of suitable and well-known optical quadratures (see, e.g., [16]), the corresponding h-dependent dynamical equations can then be reduced to a system of decoupled harmonic oscillators with space-time dependent external forces. No pre-defined global causal order is assumed other than the deterministic
time-evolution as prescribed by the Schrödinger equation. The classical $\hbar$-independent theory of Maxwell then naturally emerges in terms of properly causal and retarded expectation values of the second-quantized electromagnetic field for any initial quantum state. This is in line with more general $S$-matrix arguments due to Weinberg [17]. Thus we demonstrate explicitly that the quantized theory of electro-magnetic fields is an adequate framework for solving a whole set of classical field-theory problems. We also clarify the fundamental role of quantum-mechanical interference in comparison to classical interference, as expressed by the linearity of Maxwell’s equations.

In a straightforward manner, we have also extended this kind of presentation to a quantized theory of gravitational fluctuations around a flat Minkowski space-time, in the presence of a classical source in terms of a conserved energy-momentum tensor. From this, the weak-field limit of Einstein’s general theory of relativity emerges. Our work on this was presented in a separate publication [18].

The paper is organized as follows. In section 2 we recall, for reasons of completeness, the classical version of electrodynamics in vacuum and the corresponding issues of causality and retardation in the presence of a space-time dependent source, and the extraction of a proper set of physical but non-local degrees of freedom. The exact quantum-mechanical framework approach is illustrated in terms of a second-quantized single-mode electromagnetic field in the presence of a time-dependent classical source in section 3, where emergence of the classical $\hbar$-independent physics is also made explicit. In section 4, the analysis of section 3 is extended to multi-modes and to a general space-time dependent classical source. The issues of causality, retardation, and time-reversal are then discussed in section 5. The framework also provides for a discussion of some radiative processes, and in section 6 we consider dipole radiation, and the famous classical Vavilov-Čerenkov radiation is reproduced in a straightforward and exact manner. In section 7, we briefly discuss the role of the intrinsic quantum uncertainty of expectation values considered. Finally, in section 8, we present conclusions and final remarks. Some multi-mode considerations as referred to in the main text are presented in an appendix.

2. Maxwell’s equations with a classical source

Unless stated explicitly, we often make use of the notation $\mathbf{E} \equiv E(\mathbf{x}, t)$ for the electric field and similarly for other fields. The microscopic classical Maxwell’s equations in vacuum are then (see, e.g., [19]):

\begin{align}
\nabla \cdot \mathbf{E} & = \frac{\rho}{\varepsilon_0}, \\
\nabla \cdot \mathbf{B} & = 0, \\
\nabla \times \mathbf{E} & = -\frac{\partial \mathbf{B}}{\partial t}, \\
\nabla \times \mathbf{B} & = \mu_0 \mathbf{j} + \varepsilon_0 \mu_0 \frac{\partial \mathbf{E}}{\partial t},
\end{align}

with the velocity of light in vacuum as given by $c = 1/\sqrt{\varepsilon_0 \mu_0}$. Equations (2.1) and (2.4) imply current conservation, i.e.,

\begin{align}
\frac{\partial \rho}{\partial t} + \nabla \cdot \mathbf{j} & = 0.
\end{align}

The classical Maxwell’s equations can, of course, be written in a form that is explicitly covariant under Lorentz transformations but this will not be of importance here.

The general vector identity

\begin{align}
\nabla \times (\nabla \times \mathbf{F}) & = \nabla(\nabla \cdot \mathbf{F}) - \nabla^2 \mathbf{F},
\end{align}

applied to the electric field $\mathbf{E}$, making use of Maxwell’s equations (2.3) and (2.4), implies that

\begin{align}
\frac{1}{c^2} \frac{\partial^2 \mathbf{E}}{\partial t^2} - \nabla^2 \mathbf{E} & = -\mu_0 \frac{\partial \mathbf{j}}{\partial t} - \nabla \left( \frac{\rho}{\varepsilon_0} \right),
\end{align}

with retarded as well as advanced solutions. By physical arguments one selects the retarded solution, even though Maxwell’s equations are invariant under time-reversal as, e.g., discussed by Rohrlich [6].

We now write the electric field $\mathbf{E}$ and the magnetic field $\mathbf{B}$ in terms of the vector potential $\mathbf{A}$ and the scalar potential $\phi$, i.e.,

\begin{align}
\mathbf{E} & = -\frac{\partial \mathbf{A}}{\partial t} - \nabla \phi,
\end{align}
and
\[ \mathbf{B} = \nabla \times \mathbf{A}. \]  
(2.9)
The Coulomb (or radiation) gauge, which, of course, is not Lorentz covariant, is defined by the requirement
\[ \nabla \cdot \mathbf{A} = 0, \]  
(2.10)
and therefore leads to at most two physical degrees of freedom of the electromagnetic field. A defined with this
gauge-choice restriction is denoted by \( \mathbf{A}_F \). By making use of the vector identity equation (2.6) with \( \mathbf{F} = \mathbf{A}_F \),
Ampère’s law, i.e., equation (2.3), may then be written in the form
\[ \frac{\partial^2 \mathbf{A}_T}{\partial t^2} - c^2 \nabla^2 \mathbf{A}_T = \frac{j}{\varepsilon_0}, \]  
(2.11)
where we have introduced a transverse current \( j_T \) according to
\[ j_T \equiv j - \varepsilon_0 \frac{\partial}{\partial t} \nabla \phi. \]  
(2.12)
Equation (2.11) is, of course, the well-known wave-equation for the vector potential \( \mathbf{A}_T \) in the Coulomb gauge. The
transversality condition \( \nabla \cdot j_T = 0 \) follows from charge conservation and
\[ \nabla \cdot \mathbf{E} = -\nabla^2 \phi = \frac{\rho}{\varepsilon_0}, \]  
(2.13)
in the Coulomb gauge. Equation (2.13) is, therefore, not dynamical but should rather be regarded as a constraint
on the physical degrees of freedom in the Coulomb gauge enforcing current conservation. The instantaneous
scalar potential \( \phi \) degree of freedom can therefore be eliminated entirely in terms of the physical charge density \( \rho \)
in this context see, e.g., [20, 21]).
In passing we also recall that in the Coulomb gauge, the scalar potential \( \phi \) is, according to equation (2.13),
given by
\[ \phi(x, t) = \frac{1}{4\pi\varepsilon_0} \int d^3x' \frac{\rho(x', t)}{|x - x'|}. \]  
(2.14)
Due to the conservation of the current, i.e., equation (2.5), the time derivative of \( \phi \) may be written in the form
\[ \frac{\partial \phi(x, t)}{\partial t} = -\frac{1}{4\pi\varepsilon_0} \int d^3x' \frac{\nabla' \cdot j(x', t)}{|x - x'|}. \]  
(2.15)
According to the well-known Helmholtz decomposition theorem \( \mathbf{F} = \mathbf{F}_L + \mathbf{F}_T \) for a vector field (see, e.g., [19]),
formally written in the form
\[ \mathbf{F} = \frac{1}{\nabla^2} \left( \nabla (\nabla \cdot \mathbf{F}) - \nabla \times (\nabla \times \mathbf{F}) \right), \]  
(2.16)
using equation (2.6), we can identify the corresponding longitudinal current \( j_L \), i.e.,
\[ j_L(x, t) \equiv -\frac{1}{4\pi} \nabla \int d^3x' \frac{\nabla' \cdot j(x', t)}{|x - x'|}. \]  
(2.17)
It is now evident that the right-hand side of the wave-equation equation (2.11) for the vector potential can be
expressed in terms of the current \( j(x, t) \), i.e.,
\[ j_T(x, t) \equiv \frac{1}{4\pi} \nabla \times (\nabla \times \int d^3x' \frac{j(x', t)}{|x - x'|}). \]  
(2.18)
The important point here is that \( j_T \) is an instantaneous and non-local function in space of the physical current
\( j(x, t) \). When the Helmholtz decomposition theorem is applied to the vector potential \( \mathbf{A} = \mathbf{A}_L + \mathbf{A}_T \), it follows that the transverse part \( \mathbf{A}_T \) is gauge-invariant but, again, a non-local function in space of the vector potential \( \mathbf{A} \).
At the classical level, we now make a normal-mode Ansatz for the real-valued vector field \( \mathbf{A} \) confined in, e.g.,
a cubic box with volume \( V = L^3 \) and with periodic boundary conditions. With \( k = 2\pi(n_x, n_y, n_z)/L \), where \( n_x, n_y, n_z \) are integers, we therefore write
\[ \mathbf{A}_T(x, t) = \sum_{k} \sqrt{\frac{1}{V\varepsilon_0}} \left( q_{k}(t) \epsilon(k; \lambda) e^{ikx} + q_{k}^*(t) e^{ikx} \right), \]  
(2.19)
with time-dependent Fourier components \( q_{k}(t) \). The, in general, complex-valued polarization vectors \( \epsilon(k; \lambda) \)
obeys the transversality condition \( k \cdot \epsilon(k; \lambda) = 0 \). They are normalized in such a way that
\[ P_j \equiv P_j(k) \equiv \sum_{\lambda} \epsilon_j^*(k; \lambda) \epsilon_j(k; \lambda) = \delta_{ij} - \hat{k}_i \hat{k}_j, \]  
(2.20)
where we have defined the unit vector $\hat{\mathbf{k}} \equiv \mathbf{k}/|\mathbf{k}|$. In the case of linear polarization the real-valued, orthonormal, and linear polarization unit vectors $\mathbf{e}(\mathbf{k}; \lambda)$, with $\lambda = 1, 2$, are such that $\epsilon_1(-\mathbf{k}; \lambda) = (-1)^{\lambda+1}\epsilon_1(\mathbf{k}; \lambda)$. Since $\mathbf{A}_T$ itself is independent of the actual realization of the polarization degrees of freedom $\mathbf{e}(\mathbf{k}; \lambda)$, it is without any difficulty to express equation (2.19) in terms of, e.g., the complex circular polarization vectors with $\lambda = \pm i$, i.e.,

$$
\mathbf{e}(\mathbf{k}; \pm) = \frac{1}{\sqrt{2}}(\mathbf{e}(\mathbf{k}; 1) \pm i\mathbf{e}(\mathbf{k}; 2)),
$$

(2.21)
such that $\mathbf{e}(-\mathbf{k}; \pm) = \mathbf{e}^*(\mathbf{k}; \pm)$.

The Ansatz equation (2.19) for $\mathbf{A}_T$ is, of course, consistent with transversality of the current $j_T$ in equation (2.11). Due to the transversality of $j_T$, we can then also write that

$$
j_T(x, t) = \sum_{\mathbf{k} \lambda} \sqrt{\frac{e_0}{V}} (\tilde{j}_{\mathbf{k}\lambda}(t) \mathbf{e}(\mathbf{k}; \lambda)e^{i\mathbf{k}\cdot\mathbf{x}} + j^*_{\mathbf{k}\lambda}(t) \mathbf{e}^*(\mathbf{k}; \lambda)e^{-i\mathbf{k}\cdot\mathbf{x}}).
$$

(2.22)

The time-dependence of $q_{\mathbf{k}\lambda}(t)$ is now determined by the dynamical equation equation (2.11) for $\mathbf{A}_T$, i.e.,

$$
\ddot{q}_{\mathbf{k}\lambda}(t) + \omega^2_{\mathbf{k}} q_{\mathbf{k}\lambda}(t) = \tilde{j}_{\mathbf{k}\lambda}(t),
$$

(2.23)

with $\omega_{\mathbf{k}} = e|\mathbf{k}|$. If we define classical real-valued quadratures

$$
Q_{\mathbf{k}\lambda}(t) \equiv q_{\mathbf{k}\lambda}(t) + q^*_{\mathbf{k}\lambda}(t),
$$

(2.24)

then

$$
Q_{\mathbf{k}\lambda}(t) + \omega^2_{\mathbf{k}} Q_{\mathbf{k}\lambda}(t) = \tilde{j}_{\mathbf{k}\lambda}(t) + j^*_{\mathbf{k}\lambda}(t) \equiv f_{\mathbf{k}\lambda}(t).
$$

(2.25)

This equation has the same form as the dynamical equation for a time-dependent forced harmonic oscillator. The corresponding quantum dynamics will be treated in the next session.

3. Single mode considerations

As seen in the previous section, a single mode of the electromagnetic field reduces to a dynamical system equivalent to a forced harmonic oscillator with a time-dependent external force. The quantization of such a system is well-known (see, e.g., [22–27]) and is presented here in a form suitable for illustrating a calculational procedure to be used in later sections for finite time intervals.

With only one mode present, we write $Q \equiv Q_{\mathbf{k}\lambda}(t)$, $\omega \equiv \omega_{\mathbf{k}}$, as well as $f(t) \equiv f_{\mathbf{k}\lambda}(t)$. Equation (2.25) then takes the form

$$
\ddot{Q} + \omega^2 Q = f(t).
$$

(3.1)

This classical equation of motion can, of course, be obtained from the classical time-dependent Hamiltonian $H_{cl}(t)$ for a forced harmonic oscillator with unit mass, i.e.,

$$
H_{cl}(t) = \frac{p^2}{2} + \frac{1}{2}\omega^2 Q^2 - f(t)Q.
$$

(3.2)

We quantize this classical system by making use of the canonical commutation relation

$$
[Q, P] = i\hbar.
$$

(3.3)

We express $Q$ and $P$ in terms of the quantum-mechanical quadratures

$$
Q = \frac{\hbar}{\sqrt{2\omega}}(a + a^*),
$$

(3.4)

as well as

$$
P = i\frac{\hbar\omega}{\sqrt{2\omega}}(a^* - a),
$$

(3.5)

where $[a, a^*] = 1$. The classical Hamiltonian $H_{cl}(t)$ is then promoted to the explicitly time-dependent quantum-mechanical Hamiltonian $H(t)$ according to

$$
H_{cl}(t) \rightarrow H(t) = \hbar\omega\left(a^*a + \frac{1}{2}\right) + g(t)(a + a^*) + f(t),
$$

(3.6)

where we have defined

$$
g(t) \equiv -f(t)\frac{\hbar}{\sqrt{2\omega}}.
$$

(3.7)
In general, it is notoriously difficult to solve the Schrödinger equation with an explicitly time-dependent Hamiltonian. Due to the at most quadratic dependence of $a$ and $a^\dagger$ in equation (3.6) it is, however, easy to solve exactly for the unitary quantum dynamics. Indeed, if one considers the dynamical evolution of the system in the interaction picture with $|\psi(t)\rangle_I \equiv \exp(i\hbar H_0 / \hbar) |\psi(t)\rangle$, where we for convenience make the choice $t_0 = 0$ of initial time, then

$$i\hbar \frac{d|\psi(t)\rangle_I}{dt} = H_I(t)|\psi(t)\rangle_I. \tag{3.8}$$

For observables $\mathcal{O}$ in the interaction picture we also have that

$$\mathcal{O}_I(t) \equiv \exp(i\hbar H_0 / \hbar) \mathcal{O} \exp(-i\hbar H_0 / \hbar). \tag{3.9}$$

In our case $H_0 = \hbar \omega (a^\dagger a + 1/2)$ and therefore

$$H_I(t) = g(t)(ae^{-i\omega t} + a^\dagger e^{i\omega t}). \tag{3.10}$$

The explicit solution for $|\psi(t)\rangle_I$ is then given by

$$|\psi(t)\rangle_I = \exp\left(\frac{i}{\hbar} \phi(t)\right) \exp\left(-\frac{i}{\hbar} \int_0^t dt' H_I(t')\right) |\psi(0)\rangle, \tag{3.11}$$

for any initial pure state $|\psi(0)\rangle$. Equation (3.11) can easily be verified by, e.g., considering the limit $\Delta t \to 0$ of $(|\psi(t + \Delta t)\rangle_I - |\psi(t)\rangle_I) / \Delta t$ using that $\exp(A + B) = \exp(A) \exp(B) \exp(-[A, B] / 2)$ if $[A, B]$ is a c-number. The c-number phase $\phi(t)$ can then be computed according to

$$i\phi(t) = \frac{1}{2\hbar} \int_0^t dt' [N(t'), H_I(t')] = \frac{1}{2\hbar} \int_0^t dt' \int_0^{t'} dt'' [H_I(t''), H_I(t')], \tag{3.12}$$

with

$$N(t) \equiv \int_0^t dt' H_I(t'). \tag{3.13}$$

since, in our case, $[N(t'), H_I(t')]$ is a c-number. We therefore see that, apart from a phase, the time-evolution in the interaction picture is controlled by a conventional displacement operator as used in various studies of coherent states (see, e.g., [28, 29] and references cited therein).

The expectation value of the quantum-mechanical quadrature $Q$ in equation (3.4) at time $t$, i.e.,

$$\langle Q(t) \rangle = \langle \psi(t)|Q|\psi(t)\rangle = \langle \psi(t)|Q_I(t)|\psi(t)\rangle_I,$$

can now easily be evaluated for an arbitrary initial pure state $|\psi(0)\rangle$ with the result

$$\langle Q(t) \rangle = \langle Q \rangle \cos(\omega t) + \frac{1}{\omega} \langle P \rangle \sin(\omega t) + \frac{1}{\omega} \int_0^t dt' \sin(\omega(t - t')),$$

where $\langle \mathcal{O} \rangle \equiv \langle \mathcal{O} \rangle(0)$ for the initial expectation value of an observable $\mathcal{O}$. In equation (3.14) we, of course, recognize the general classical solution of the forced harmonic oscillator equations of motion equation (3.1), i.e.,

$$\frac{d^2}{dt^2} \langle Q \rangle(t) + \omega^2 \langle Q \rangle(t) = f(t), \tag{3.15}$$

in terms of its properly retarded Green’s function (see, e.g., [30]). The last term in equation (3.14) is classical in the sense that it does not depend on $\hbar$. Possible quantum-interference effects are hidden in the homogeneous solution of equation (3.15).

Similarly, we find for the $P$-quadrature in equation (3.5) that $\langle P \rangle(t) = d\langle Q \rangle(t)/dt$ or more explicitly:

$$\langle P \rangle(t) = \langle P \rangle \cos(\omega t) - \langle Q \rangle \omega \sin(\omega t) + \int_0^t dt' \cos(\omega(t - t')). \tag{3.16}$$

Even though the classical equation of motion emerges in terms of quantum-mechanical expectation values, intrinsic quantum uncertainty for any observable $\mathcal{O}$ as defined by

$$\langle \Delta \mathcal{O} \rangle^2(t) \equiv \langle \psi(t)|(\mathcal{O} - \langle \mathcal{O} \rangle^2)|\psi(t)\rangle,$$

is in general present. For $\mathcal{O} = Q$ one finds that

$$\langle \Delta Q \rangle^2(t) = \langle \Delta Q \rangle^2 \cos^2 \omega t + \langle \Delta P \rangle^2 \frac{\sin^2 \omega t}{\omega^2} + \frac{\cos \omega t \sin \omega t}{\omega} \langle PQ + QP - 2\langle Q \rangle \langle P \rangle \rangle, \tag{3.17}$$

independent of the external force $f(t)$. For minimal dispersion states, i.e., states for which $\Delta Q \Delta P = \hbar / 2$, the last term is zero. For coherent states one then finds the intrinsic and time-independent quantum-mechanical uncertainty $\langle \Delta Q \rangle^2(t) = \hbar / 2\omega$ and $\langle \Delta P \rangle^2(t) = \hbar \omega / 2$. 

The classical equation of motion equation (3.15) allows for linear superpositions of solutions. Such linear superpositions are, however, not directly related to quantum-mechanical superpositions of the initial quantum states since expectation values are non-linear functions of quantum states. For number states \( |n\rangle \), with \( a|0\rangle = 0 \), which in terms of, e.g., a Wigner function have no classical interpretation except for the vacuum state \( |0\rangle \) (see, e.g., [16]), we have that \( \langle Q \rangle = \langle P \rangle = 0 \) but \( (\Delta Q)^2(t) = (\Delta P)^2(t) / \omega^2 = (n + 1/2) \hbar / \omega \). For an initial state of the form \( |\psi(0)\rangle = (|0\rangle + |1\rangle) / \sqrt{2} \) we find that \( \langle Q \rangle = \sqrt{\hbar / 2}\omega \) and \( \langle P \rangle = 0 \) with an intrinsic time-dependent quantum uncertainty, e.g., \( (\Delta Q)^2(t) = \hbar (2 - \cos^2 \omega t) / 2\omega \). This initial state therefore leads to expectation values that do not correspond to a superposition of the classical solutions obtained from the initial states \( |0\rangle \) or \( |1\rangle \). This simple example demonstrates the fundamental difference between the role of the superposition principle in classical and in quantum physics. It is a remarkable achievement of experimental quantum optics that such quantum-mechanical interference effects between the vacuum state and a single-photon state have been observed [31, 32] (for a related discussion also see [33–37]). In the next section we extend this simple single-mode case to the general multi-mode space-time dependent situation.

4. Multi-mode considerations

We will now consider emission as well as absorption processes of photons in the presence of a general space-time dependent classical source as illustrated in figure 1. In the multi-mode case the interaction Hamiltonian \( H_I(t) \) for a classical current \( j(x, t) \) is now an extension of the single-mode version equation (3.10). In the Coulomb gauge and in the interaction picture, we therefore consider

\[
H_I(t) = -\int_V d^3x \, j(x, t) \cdot A_F(x, t)
\]

\[
= -\sum_{k\lambda} \left( \hbar / 2V\epsilon_0 \omega_k \right) \left( j(k, t) \cdot \epsilon(k; \lambda) a_{k\lambda} e^{-i\omega_k t} + j^*(k, t) \cdot \epsilon^*(k; \lambda) a_{k\lambda}^* e^{i\omega_k t} \right),
\]

with the ‘free’ field Hamiltonian

\[
H_0 = \sum_{k\lambda} \hbar \omega_k \left( a_{k\lambda}^* a_{k\lambda} + 1 / 2 \right).
\]

Here we have introduced the Fourier transformed current

\[
j(k, t) \equiv \int_V d^3x \, e^{i\mathbf{k} \cdot \mathbf{x}} j(x, t).
\]

Since \( j_x(k, t) = \hat{k} (\hat{k} \cdot j(k, t)) \) and \( j_y(k, t) = j(k, t) - j_x(k, t) \), it is clear due to the transversality condition \( \mathbf{k} \cdot \epsilon(k; \lambda) = 0 \) that only the transverse part of the current contributes in equation (4.1).

The interaction equation (4.1) therefore corresponds to a system of independent forced harmonic oscillators of the one-mode form as discussed in the previous section. The second-quantized version of the vector-potential in equation (2.19) then has the form of a free quantum field, i.e.,

\[\text{Figure 1. Absorption and emission of photons from a classical current } j(x, t).\]
\[ A_T(x, t) = \sum_{k \lambda} \sqrt{\frac{\hbar}{2V_0 \omega_k}} \left( a_{k \lambda} \varepsilon(k; \lambda) e^{i(k \cdot x - \omega_k t)} + a_{k \lambda}^* \varepsilon^*(k; \lambda) e^{-i(k \cdot x - \omega_k t)} \right), \]  

(4.4)

with the basic canonical commutation relation
\[ [a_{k \lambda}, a_{k' \lambda'}^*] = \delta_{\lambda \lambda'} \delta_{k k'}, \]

and where we recall that \( \omega_k = c|k| \). The vacuum state \( |0\rangle \) is then such that \( a_{k \lambda} |0\rangle = 0 \) for all quantum numbers \( k \lambda \). The quantum field \( A_T \) is then normalized in such a way that
\[ H_0 = \int_V d^3 x \left( \frac{1}{2} \varepsilon_0 E_T^2(x, t) + \frac{1}{\mu_0} B_T^2(x, t) \right), \]

(4.6)

where, for the free field in equation (4.4), we make use of \( E_T = -\partial A_T / \partial t \) and \( B \equiv \nabla \times A = \nabla \times A_T \).

If we consider the circular polarization vectors \( \varepsilon(k; \pm) \) according to equation (2.21), we have to replace the annihilation operators \( a_{k \lambda} \) with
\[ a_{k \pm} = \frac{1}{\sqrt{2}} (a_{k1} \mp i a_{k2}). \]

(4.7)

We then observe that
\[ \sum_{\lambda = 1,2} \varepsilon(k; \lambda) a_{k \lambda} = \sum_{\lambda = \pm} \varepsilon(k; \lambda) a_{k \lambda}, \]

(4.8)

which means that the quantum field \( A_T \) does not depend on the actual realization of the choice of polarization degrees of freedom.

The single photon quantum states \( |k \lambda\rangle \equiv a_{k \lambda}^* |0\rangle \), with \( \lambda = \pm \), will then carry the energy \( \hbar \omega_k \), momentum \( \hbar k \) as well as the intrinsic spin angular momentum \( \pm \hbar \) along the direction \( \hat{k} \), i.e., the helicity quantum number of a massless spin-one particle. In passing, we remark that the latter property can be inferred from a consideration of a rotation with an angle \( \theta \) around the wave-vector \( \hat{k} \) in terms of a rotation matrix \( R_\theta(\hat{k}) \), which implies that \( a_{k \lambda} \rightarrow a_{R_\theta(\hat{k}) k \lambda} = \exp(\pm i \theta) a_{k \lambda} \). In terms of the corresponding rotated polarization vectors \( \varepsilon_i(k; \lambda \theta) = R_\theta(\hat{k}) \varepsilon_i(k; \lambda) \) we then have, in accordance with equation (4.8), that
\[ \sum_{\lambda = 1,2} \varepsilon(k; \lambda) a_{k \lambda} = \sum_{\lambda = \pm} \varepsilon(k; \lambda \theta) a_{k \lambda}(\theta). \]

(4.9)

In addition to the intrinsic spin angular momentum, photon states can also carry conventional orbital angular momentum which plays an important role in many current contexts (see, e.g., [38] and references cited therein) but will not be of concern in the present work. A complete set of physical and well-defined Fock-states can then be generated in a conventional manner. By construction, these states have positive norm avoiding the presence of indefinite norm states in manifestly covariant formulations (for some considerations see, e.g., [39–41]).

Since, obviously,
\[ \int_0^t dt' H_1(t') = -\sum_{k \lambda} \sqrt{\frac{\hbar}{2V_0 \omega_k}} \int_0^t dt' \left( a_{k \lambda} e^{-i \omega_k t'} \varepsilon(k; \lambda) \cdot j(k, t') + a_{k \lambda}^* e^{i \omega_k t'} \varepsilon^*(k; \lambda) \cdot j^*(k, t') \right), \]

(4.10)

we conclude that the time-evolution for \( |\psi(t)\rangle \) in equation (3.11) is, apart from a phase factor, given by a multi-mode displacement operator
\[ D(\alpha) \equiv \exp \left( -\frac{i}{\hbar} \int_0^t dt' H_1(t') \right) = \prod_{k \lambda} \exp \left( \alpha_{k \lambda}(t) a_{k \lambda}^* - \alpha_{k \lambda}^*(t) a_{k \lambda} \right). \]

(4.11)

Here \( \alpha_{k \lambda}(t) \) is, as inferred from equation (4.10), explicitly given by
\[ \alpha_{k \lambda}(t) \equiv \frac{i}{\hbar} \sqrt{\frac{\hbar}{2V_0 \omega_k}} \int_0^t dt' e^{i \omega_k t'} j^*(k, t') \cdot e^*(k; \lambda), \]

with \( j^*(k, t) = j(-k, t) \). The displacement operator \( D(\alpha) \) has the form of a product of independent single-mode displacement operators. By making use of equation (3.11), and by considering the action on the vacuum state, the quantum-mechanical time-evolution generates a multi-mode coherent state \( D(\alpha) |0\rangle \), apart from the \( \hbar \)-dependent phase \( \phi(t) \) in equation (3.11). As in the single-mode case, the time-dependent expectation value of the transverse quantum field \( A_T(x, t) \) will then obey a classical equation of motion similar to equation (3.15), i.e., (see appendix)
\[ \frac{\partial^2 \langle A_T(x, t) \rangle}{\partial t^2} - c^2 V^2 \langle A_T(x, t) \rangle = \frac{J_T(x, t)}{\epsilon_0}, \]

(4.12)
to be investigated in more detail in section 5. In other words, there are particular quantum states of the radiation field, namely multi-mode coherent states, which naturally lead to the classical electromagnetic fields obeying Maxwell’s equations equations (2.1)–(2.4) in terms of quantum–mechanical expectation values.

5. The causality issue

The expectation value of the transverse second–quantized vector field $A_T$ is now given by equation (A.4), i.e.,

$$
\langle A_T(x, t) \rangle = \int \frac{d^3k}{(2\pi)^3} e^{ikx} \int_0^\infty dt \sin(\omega_k(t-t')) \int \frac{d^3x'}{2\pi^3} e^{-ikx'} j_T(x', t') ,
$$

(5.1)

where we have carried out a sum over polarizations according to equation (2.20) as in equation (A.5), and where the sum over $k$ in the large volume $V$ limit is replaced by

$$
\sum_k = \frac{V}{(2\pi)^3} \int d^3k .
$$

(5.2)

The Fourier transform of the transverse current vector in equation (5.1) is as above given by

$$
\langle j_T(x, t) \rangle = \int d^3x e^{ikx} j_T(x, t) .
$$

(5.3)

The time-derivative of equation (5.1) can now be written in the form

$$
\frac{\partial \langle A_T(x, t) \rangle}{\partial t} = \int \frac{d^3k}{(2\pi)^3} \int_0^\infty dt \frac{\partial}{\partial t} G(x - x', t - t') (\langle j(x', t') \rangle - \langle j(x', t') \rangle),
$$

(5.4)

by making use of the Helmholtz decomposition of the current vector $j(x, t)$, and where we identified the Green’s function $G(x, t)$

$$
G(x, t) = \lim_{V \to \infty} \int \frac{d^3k}{(2\pi)^3} \frac{e^{ikx}\sin(\omega_k t)}{\omega_k} = \frac{1}{4\pi c^3|x|} (\delta(t - |x|/c) - \delta(t + |x|/c)).
$$

(5.5)

This Green’s function is a solution to the homogeneous wave-equation

$$
\frac{\partial^2 G(x, t)}{\partial t^2} = c^2 \nabla^2 G(x, t),
$$

(5.6)

such that $G(x, t) = 0$ and $\partial G(x, t)/\partial t = 0$ at $t = 0$. For the second term in equation (5.4) we need to consider the integral

$$
I = \int d^3x' \int_0^\infty dt \frac{\partial}{\partial t} G(x - x', t - t') \nabla' \frac{\partial}{\partial t} \phi(x', t') .
$$

(5.7)

This is so since the longitudinal vector current $j_L(x, t)$ may be written in the form

$$
j_L(x, t) = \frac{\partial}{\partial t} \frac{1}{4\pi} \nabla \int d^3x' \frac{\rho(x', t)}{|x - x'|} = \frac{\epsilon_0}{\epsilon_0} \frac{\partial}{\partial t} \nabla \phi(x, t) ,
$$

(5.8)

where we make use of the Helmholtz decomposition equation (2.17) and current conservation. After a partial integration in the time variable $t'$ and by making use of equation (5.6), the integral $I$ can therefore be written in the following form

$$
I = \nabla \phi(x, t) + \frac{c^2}{\epsilon_0} \int d^3x' \int_0^t dt' \nabla' G(x - x', t - t') \nabla' \phi(x', t'),
$$

(5.9)

where we have used the fact that $\partial G(x, t)/\partial t = \delta^3(x)$ at $t = 0$ as well as the initial condition $j_L(x, 0) = 0$ for all $x$. We now perform two partial integrations over the spatial variable and by using equation (2.13), we finally see that

$$
I = \nabla \phi(x, t) - \frac{c^2}{\epsilon_0} \int d^3x' \int_0^t dt' G(x - x', t - t') \nabla' \rho(x', t'),
$$

(5.10)

neglecting spatial boundary terms and using the initial condition $\rho(x, 0) = 0$ for all $x$. The first term in equation (5.10) exactly cancels the instantaneous Coulomb potential contribution in the expectation value of the quantized electric field observable

$$
\langle E(x, t) \rangle = -\frac{\partial \langle A_T(x, t) \rangle}{\partial t} - \nabla \phi(x, t) .
$$

(5.11)
For $t' > t$, we therefore obtain the desired result

$$
\langle \mathbf{E}(\mathbf{x}, t) \rangle = -\frac{\partial}{\partial t} \left( \frac{1}{4\pi\epsilon_0 c^2} \int d^3\mathbf{x}' \frac{j(\mathbf{x}', t - |\mathbf{x} - \mathbf{x}'|/c)}{|\mathbf{x} - \mathbf{x}'|} \right) - \frac{1}{4\pi}\int d^3\mathbf{x}' \frac{\nabla' \rho(\mathbf{x}', t - |\mathbf{x} - \mathbf{x}'|/c)}{|\mathbf{x} - \mathbf{x}'|},
$$

(5.12)

where $\nabla' \rho(\mathbf{x}', t')$ in equation (5.12) has to be evaluated for a fixed value of $t' = t - |\mathbf{x} - \mathbf{x}'|/c$. In a similar manner we also see that

$$
\langle \mathbf{B}(\mathbf{x}, t) \rangle = \nabla \times \langle \mathbf{A}_f(\mathbf{x}, t) \rangle = \frac{1}{16\pi} \int d^3\mathbf{x}' \int_0^{t'} dt' G(\mathbf{x} - \mathbf{x}', t - t') \nabla' \times j_\mathbf{f}(\mathbf{x}', t')
$$

$$
= \frac{\mu_0}{4\pi} \int d^3\mathbf{x}' \frac{1}{|\mathbf{x} - \mathbf{x}'|} \nabla' \times j(\mathbf{x}', t - |\mathbf{x} - \mathbf{x}'|/c),
$$

(5.13)

since $\nabla' \times j_f(\mathbf{x}', t') = \nabla' \times j(\mathbf{x}', t')$. In equation (5.13), we remark again that $\nabla' \times j(\mathbf{x}', t')$ has to be evaluated for a fixed value of $t' = t - |\mathbf{x} - \mathbf{x}'|/c$. The causal and properly retarded form of the electric and magnetic quantum field expectation values in terms of the physical and local sources given have therefore been obtained (see in this context, e.g., [19], section 6.5).

The expectation values as given by equations (5.12) and (5.13) obey Maxwell’s equations in terms of the classical charge density $\rho$ and current $J$. The quantization procedure above of the electromagnetic field explicitly breaks Lorentz covariance. Since, however, Maxwell’s equations transform covariantly under Lorentz transformations we can, nevertheless, now argue that the special theory of relativity emerges in terms of expectation values of gauge-invariant second-quantized electromagnetic fields.

Maxwell’s equations of motion according to equations (2.1)–(2.4) are invariant under the discrete time-reversal transformation $t \rightarrow t' = -t$ with $\mathbf{E}(\mathbf{x}, t) \rightarrow \mathbf{E}'(\mathbf{x}, t) = \mathbf{E}(\mathbf{x}, -t)$ and $\mathbf{B}(\mathbf{x}, t) \rightarrow \mathbf{B}'(\mathbf{x}, t) = -\mathbf{B}(\mathbf{x}, -t)$ provided $j(\mathbf{x}, t) \rightarrow j'(\mathbf{x}, t) = -j(\mathbf{x}, -t)$ and $\rho(\mathbf{x}, t) \rightarrow \rho'(\mathbf{x}, t) = \rho(\mathbf{x}, -t)$. At the classical level, the corresponding transverse vector potential transforms according to $\mathbf{A}_f(\mathbf{x}, t) \rightarrow \mathbf{A}'_f(\mathbf{x}, t) = -\mathbf{A}_f(\mathbf{x}, -t)$. The anti-unitary time-reversal transformation $T$ is implemented on second-quantized fields in the interaction picture according to the rule (see, e.g., [20, 42–44])

$$
\langle \psi(\mathbf{t})| \mathbf{A}_f(\mathbf{x}, t) |\psi(\mathbf{t})\rangle \rightarrow T \langle \psi(\mathbf{t})| \mathbf{A}'_f(\mathbf{x}, t) |\psi(\mathbf{t})\rangle = \langle \psi(-\mathbf{t})| T \mathbf{A}_f(\mathbf{x}, t) T^{-1} |\psi(-\mathbf{t})\rangle.
$$

(5.14)

It then follows that $\langle \psi(\mathbf{t})| \mathbf{A}_f(\mathbf{x}, t) |\psi(\mathbf{t})\rangle = -\langle \psi(\mathbf{t})| \mathbf{A}_f(\mathbf{x}, t) |\psi(\mathbf{t})\rangle$ if $T = e^{-i\omega_\mathbf{k}_\lambda T} = a_{-\mathbf{k}_\lambda}(-1)\mathbf{i}$ and provided the vacuum state $|0\rangle$ is invariant under time-reversal. We therefore find that $\langle \mathbf{A}_f(\mathbf{x}, t) | = -\langle \mathbf{A}_f(\mathbf{x}, -t) |$. We therefore obtain $\langle \mathbf{E}(\mathbf{x}, t) | = \langle \mathbf{E}(\mathbf{x}, -t) |$ and $\langle \mathbf{B}(\mathbf{x}, t) | \rightarrow -\langle \mathbf{B}(\mathbf{x}, -t) |$ as it should. Due to the form of the Green’s function $G(\mathbf{x}, t)$ in equation (5.5) it can be verified that equation (5.1) also leads to expectation values $\langle \mathbf{E}(\mathbf{x}, t) |$ and $\langle \mathbf{B}(\mathbf{x}, t) |$ that transform correctly under time-reversal.

The arrow of time can therefore, as expected, not be explained by our approach but as soon as the direction of time is defined the observable quantities $\langle \mathbf{E}(\mathbf{x}, t) |$ and $\langle \mathbf{B}(\mathbf{x}, t) |$ are causal and properly retarded. In the presence of external sources we could have an apparent breakdown of time-reversal invariance unless one also time-reverses the external sources.

### 6. Electromagnetic radiation processes

The rate for spontaneous emission of a photon from, e.g., an excited hydrogen atom can now be obtained in a straightforward manner in terms of a slight extension of the interaction equation (4.10) as to be made use of in first-order time-dependent perturbation theory. We then make use of the long wave-length approximation

$$
j(\mathbf{x}, t) \approx \int d^3\mathbf{x}' j(\mathbf{x}', t) = \frac{\partial}{\partial t} \int d^3\mathbf{x} \rho(\mathbf{x}, t) = \frac{q}{\hbar} \frac{d}{dt} \mathbf{x}(t),
$$

(6.1)

taking current conservation equation (2.5) into account, where $\rho(\mathbf{x}, t) = \rho^{(3)}(\mathbf{x} - \mathbf{x}(t))$ in terms of the position $\mathbf{x}(t)$ of the charged electron in the interaction picture. For the spontaneous single photon transition $|\psi\rangle \rightarrow |f\rangle$ with $|\psi\rangle = |a_i\rangle \otimes |0\rangle$ and $|f\rangle = |a_j\rangle \otimes |\mathbf{k}\lambda\rangle$, we then arrive at the standard dipole radiation first-order matrix element

$$
\langle f|H_t(0)|\psi\rangle = i e \frac{\hbar}{2V\epsilon_0 \omega_k} \mathbf{e} \cdot |a_j\rangle \langle a_i|,
$$

(6.2)

using equation (4.10) with $q = -e$ in the interaction picture. The relevant matrix element $\langle a_i|\mathbf{x}(t)|a_j\rangle$ is then given by $\exp(-i\omega_k t) \langle a_i|\mathbf{x}|a_j\rangle$. For the atomic transition from $|a_i\rangle = |nlm\rangle = |2p\rangle$ to the final atomic ground state $|a_f\rangle = |1s\rangle$, the corresponding rate is then given by
\[ \Gamma \equiv \frac{2\pi}{\hbar^2} \sum_{\mathbf{k}} \delta(\omega_k - \omega_f) \| \langle \hat{H}_f(0) \rangle \|^2 = \left( \frac{2}{3} \right)^{\alpha} \frac{e^4}{\alpha_0^3}, \quad (6.3) \]

in terms of the fine-structure constant \( \alpha \equiv \frac{e^2}{4\pi\varepsilon_0\hbar c} \) and the Bohr radius \( a_B \). The rate \( \Gamma \) is independent of the quantum number \( m \). Stimulated emission gives rise to a multiplicative factor \((1 + n_{k\alpha})\). Equation (6.3) is, of course, a well-known text-book result in agreement with the experimental value (see, e.g., [45]). The considerations above can be extended to graviton quadrupole radiation processes in an analogous manner [18].

The power of electromagnetic emission from a classical conserved electric current in, e.g., a non-dissipative dielectric medium and the famous Vavilov-Čerenkov [46] radiation can, furthermore, now also be derived in terms of the quantum-mechanical framework above. This form of radiation was first explained by Frank and Tamm [47] using the framework of Maxwell’s classical theory of electromagnetism. The exact classical \( h \)-independent expression for the power of Vavilov-Čerenkov radiation (see, e.g., Section 13.4 in [19]), neglecting possible spin effects to be discussed elsewhere [48], can now be obtained as follows. For a particle with electric charge \( q \), mass \( m \), and an initial velocity \( v \), moving in dielectric medium such that \( \varepsilon_0 = \varepsilon_0, \) with \( \varepsilon > 1, \) the interaction \( H_f(t) \) in equation (4.10) leads to a displacement operator with \( \alpha_{k\alpha}(t) \) now replaced by

\[
\alpha_{k\alpha}(t) = \frac{i}{\hbar} \sqrt{\frac{\hbar}{2V\varepsilon_0\omega_k}} \int_{t_0}^{t} dt' e^{i\omega_k t'} \int d^3x j(x, t') \cdot \varepsilon^*(\mathbf{k}; \lambda) e^{-i\mathbf{k} \cdot \mathbf{x}} \]

\[
= \frac{q}{\varepsilon_0} \sqrt{\frac{\hbar}{2V\varepsilon_0\omega_k}} \mathbf{v} \cdot \varepsilon^*(\mathbf{k}; \lambda) \int_{t_0}^{t} dt' e^{i(\omega_k - \mathbf{k} \cdot \mathbf{v})t'}, \quad (6.4)
\]

where the relativistic current \( j(x, t) \) in an inertial frame is given by

\[ j(x, t) = q\mathbf{v} \delta^{(3)}(x - vt). \]

The power \( P(\omega)d\omega \) of emitted radiation in the range \( \omega \) to \( \omega + d\omega \) is then obtained by evaluating the exact expression \( d\langle H_f \rangle(t)/dt \), using equation (6.4), where

\[ \frac{d\langle H_f \rangle(t)}{dt} = \frac{d}{dt} \sum_{k\alpha} |\alpha_{k\alpha}(t)|^2 \equiv \int_{0}^{\omega} d\omega P(\omega), \quad (6.5) \]

in the large volume \( V \) limit, and by considering the large \( T \equiv t - t_0 \) limit. The cut-off angular frequency \( \omega_c \equiv mc^2/\hbar \) is to be determined in a standard manner taken the \( \omega \)-dependence of \( \varepsilon \) into account (see, e.g., [19]). Here we can, of course, disregard the additive divergent zero-point fluctuations in \( \langle H_f \rangle(t) \). The large \( T \) limit leads to a phase-matching condition \( \omega_k = \mathbf{k} \cdot \mathbf{v} = nk \cos \theta_c, \) using \( \mathbf{v} \equiv |\mathbf{v}| \) and \( k \equiv |\mathbf{k}| \), expressed in terms of the well-known Čerenkov angle \( \cos \theta_c \equiv c/nv \), where \( \omega_k = ck/\hbar \) with the refractive index \( n \equiv \sqrt{\varepsilon} \). The \( \lambda \)-sum over the polarization degrees of freedom in equation (6.6) leads to

\[ \sum_{\lambda=1,2} |(\mathbf{v} \cdot \varepsilon(\mathbf{k}; \lambda))|^2 = |\mathbf{v}|^2 (1 - \cos^2 \theta_c), \quad (6.7) \]

using equation (2.20), where, in general, \( \cos \theta \equiv \mathbf{v} \cdot \frac{1}{\sqrt{\varepsilon}} \) in terms of the unit vectors. In summing over the angular distribution of the radiation emitted in equation (6.5), the large \( T \) phase-matching condition is taken into account. We then easily find the well-known \( h \)-independent power spectrum

\[ P(\omega) = \frac{e^2}{4\pi\varepsilon_0 c} \frac{\mathbf{v}}{\omega^2} (1 - \cos^2 \theta_c). \quad (6.8) \]

Alternatively, but in a less rigorous manner, one may consider \( \langle H_f \rangle(t)/T \) and make use of equation (6.4) in the large \( T \)-limit, i.e.,

\[ \alpha_{k\alpha}(t) = 2\pi q \frac{i}{\hbar} \sqrt{\frac{\hbar}{2V\varepsilon_0\omega_k}} \delta(\omega_k - \mathbf{k} \cdot \mathbf{v}) \mathbf{v} \cdot \varepsilon^*(\mathbf{k}; \lambda). \quad (6.9) \]

By inspection we then observe that \( \alpha_{k\alpha}(t) \) in equation (6.9) exactly corresponds the quantum-mechanical amplitude for the emission of one photon from the source to first-order in time-dependent perturbation theory even though our expression for \( \alpha_{k\alpha}(t) \) is exact.

We have therefore derived a power spectrum that exactly corresponds to the 1937 Frank-Tamm expression [47] in terms of the Čerenkov angle \( \cos \theta_c \) as obtained from the \( \delta \)-function constraint in equation (6.9). In the quantum-mechanical perturbation theory language this constraint corresponds to an energy-conservation \( \delta \)-function as a well as to conservation of momentum taking the refractive index \( n \equiv \sqrt{\varepsilon} \) into account. The corresponding energy of the emitted photon is then given by \( E_\gamma = \hbar \omega \) and the Minkowski canonical momentum by \( p_\gamma = \hbar \mathbf{k} \) (see, e.g., [49]), with \( \omega = c|\mathbf{k}|/n \). The expression for the Čerenkov angle \( \cos \theta_c \) is then modified according to [50]
\[ \cos \theta_C = \frac{c}{nv} \left( 1 + \frac{\hbar \omega_k (n^2 - 1) \sqrt{1 - \frac{v^2}{c^2}}}{2mc^2} \right). \] (6.10)

As was first noted by Ginzburg ([50] and references cited therein), and also presented in various text-books accounts (see, e.g., [51, 52]), first-order perturbation theory in quantum mechanics actually leads to the same exact power spectrum for Vavilov–Cherenkov radiation. The explanation of this curious circumstance can be traced back to the fact that all higher order corrections are taken into account by the presence of the phase \( \phi(t) \) in equation (3.11).

7. Quantum uncertainty

The displacement of quantum states as induced by \( D(\alpha) \), as defined in equation (4.11), acting on an arbitrary pure initial state again leads to Maxwell’s equations for the expectation value of the quantum field changing, at most, the homogeneous solution of the expectation value of the wave-equation (4.13). The corresponding quantum uncertainty of \( E(x, t) \), however, depends on the choice of the initial state along the same reasoning as in the single-mode case in section 3. An essential and additional ingredient with regard to the approach to the classical limit is to consider the variance of, e.g., the second-quantized electromagnetic field observables averaged over some space-time point. Bohr and Rosenfeld also provided a solution of this apparent physical contradiction. The basic idea is to introduce quantum field observables averaged over some finite space-time volume. Bohr and Rosenfeld made use of a cube centered at the space-time point \( x \) which, however, makes some of the expressions obtained rather complicated. We will follow another approach which makes the expressions more tractable (see, e.g., problem 2.3 in [20]), i.e., we consider

\[ E_{s}(x, t) \equiv \int_{-\infty}^{\infty} dt' \int_{V} d^{3}x' f_{s}(x-x')f_{s}(t-t')E(x', t'), \] (7.3)

where

\[ f_{s}(x) = \frac{1}{(2\pi \sigma_{s}^{2})^{3/2}} \exp \left(-\frac{x^2}{2\sigma_{s}^{2}}\right), \] (7.4)

and

\[ f_{s}(t) = \frac{1}{(2\pi \sigma_{s}^{2})^{1/2}} \exp \left(-\frac{t^2}{2\sigma_{s}^{2}}\right). \] (7.5)

The parameter \( \sigma \) gives a characteristic scale for the space-volume around the point \( x \) where we perform the space average. Correspondingly, the parameter \( \sigma \) gives a characteristic time-scale for the time average procedure.

The linear classical Maxwell’s equations can then again be obtained as in the previous sections in terms of the quantum-mechanical average of fields like \( E_{s}(x, t) \) provided that the classical sources are space and/or time averaged in the same manner. It now follows that
\[ E_\nu(x, t) = \sum_{k\lambda} \frac{i}{\hbar} \sqrt{\frac{\hbar k}{2V_0}} \exp \left( -\frac{\sigma^2 \omega^2}{2} \right) \left( \eta_{k\lambda} e^{i(kx-\omega t)} - \eta^*_{k\lambda} e^{-i(kx-\omega t)} \right). \] (7.6)

The variance \((\Delta E_\nu(x, t))^2\) of the space and time averaged electric quantum field \(E_\nu(x, t)\), in a sufficiently large quantization volume \(V\), will then be finite and corresponds to an energy

\[ \varepsilon_0(\Delta E_\nu(x, t))^2 \sigma^3 \geq E_\nu \equiv \frac{1}{(2\pi)^3} \frac{2\pi k}{\hbar}, \] (7.7)

localized in a volume \(V_\nu \equiv \sigma^3 \ll V\), where

\[ \sigma^2 \equiv \sigma_0^2 + c^2 \sigma_1^2. \] (7.8)

It is now clear that \(E_\nu\) will be finite in the cases \(\sigma_0 = 0, \sigma_1 = 0\) as well as \(\sigma_0 = 0, \sigma_1 = 0\).

Physically, the expression in equation (7.7) corresponds, apart from an irrelevant numerical factor, to the energy of a photon with a wave-length \(\lambda \simeq \sigma\) and, hence, a wave-number \(k \simeq 2\pi/\sigma\) and therefore to an energy \(E_\nu \simeq \hbar k \simeq 2\pi \hbar / \sigma\), in a typical localization volume \(V_\nu\). It is now clear that \(E_\nu\) will tend to infinity as \(\sigma \rightarrow 0\), i.e., we would then obtain an arbitrarily large energy and/or energy density if we try to localize the quantum field in the sense above in an arbitrary small \(V_\nu\). A macroscopic field, however, corresponds to a localization volume much larger than \(V_\nu\), and therefore these quantum uncertainties can be disregarded in the classical regime.

This latter feature can be illustrated by evaluating \((\Delta E_\nu(x, t))^2\) for a thermal Planck distribution of \(\eta_{k\lambda}\) at a temperature \(T\) with a typical coherence length scale \(\sigma_T \equiv \pi k/\hbar T\). For localization scales \(\sigma \ll \sigma_T\), i.e., at sufficiently small temperatures, one then finds that \(\varepsilon_0(\Delta E_\nu(x, t))^2 \sigma^3 = E_\nu(1 + 4\pi^4/\sigma^2/15)\). The thermal induced uncertainty can therefore be neglected in comparison with \(E_\nu\) for large thermal coherence lengths \(\sigma_T\) as compared to \(\sigma\). If, on the other hand, \(\sigma_T \ll \sigma\), i.e., at sufficiently high temperatures, it follows that \(\varepsilon_0(\Delta E_\nu(x, t))^2 \sigma^3 = k_B T(1 + (\sigma_T/\sigma)^2/8)/4\pi^2/2\) and, as expected, the thermal uncertainty will then dominate at sufficiently high temperatures.

As was predicted a long time ago for single-mode quantum fields [55], it is possible to reduce the uncertainty \((\Delta E(x, t))^2\) below the vacuum value by making use of initial squeezed quantum states \(|\psi(0)\rangle\). This feature has recently been confirmed experimentally ([56] references cited therein). For multi-mode considerations, relevant for the framework of the present work, this may also be possible for \((\Delta E_\nu(x, t))^2\) but this will not be a topic in the present paper.

8. Final remarks

We have shown how a quantum-mechanical framework offers a good platform to analyze causality and retardation issues in the classical theory of Maxwell. As we have shown elsewhere, our quantum-mechanical framework can rather easily be extended to a derivation of the weak-field limit of Einstein’s general theory of relativity [18]. From second-quantization of the physical degrees of freedom under the condition of current conservation the well established classical theory for electromagnetism naturally emerges. The overwhelming experimental support for Maxwell’s classical theory does not necessarily imply the existence of photons and doubts on the existence of such quantum states are sometimes put forward (see, e.g., [57]). However, the quantum-mechanical derivation of the classical theory necessarily implies the existence of single particle quantum states corresponding to a photon.

We have also observed that various radiation processes including the classical, i.e., \(\hbar\)-independent, Vavilov-Čerenkov radiation can be obtained in a straightforward manner. It may come as a surprise that a first-order quantum-mechanical perturbation theory calculation can give an exact \(\hbar\)-independent answer. This, as it seems, remarkable fact is explained by the factorization of the time-evolution operator in terms of a displacement operator for quantum states in the interaction picture according to equation (3.11) making use of equation (4.10). The phase \(\phi(t)\) then contains the non-perturbative effects of all higher-order corrections to the first-order result.

As a matter of fact, similar features are known to occur also in some other situations. As is well-known, the famous differential cross-section for Rutherford scattering can be obtained exactly in terms of the first-order Born approximation. All higher order corrections will then contribute with an overall phase for probability amplitudes which follows from the exact solution (see, e.g., the excellent discussion in [58]). The classical Thomson cross-section for low-energy light scattering on a charged particle is also exactly obtained from a Born approximation due to the existence of an exact low-energy theorem in quantum electrodynamics (see, e.g., the discussions in [2, 3, 59]).

The authors also appreciate helpful comments from anonymous referees.

Appendix. expectation value of the quantum field $A_T(x, t)$

Apart from a phase-factor, the time-evolution in the interaction picture is controlled by the operator

$$\exp\left(-\frac{i}{\hbar} \int_0^t dt' H_i(t')\right) = \prod_{\mathbf{k}\lambda} \exp\left((\alpha_{\mathbf{k}\lambda}(t) a^\dagger_{\mathbf{k}\lambda} - \alpha^*_{{\mathbf{k}\lambda}}(t) a_{\mathbf{k}\lambda})\right),$$

(A.1)

where $\alpha_{\mathbf{k}\lambda}(t)$ is given by equation (4.12) in the main text. Since expectation values are independent of the picture used, i.e.,

$$s(\psi(t) | \mathcal{O}| \psi(t)) = i(\psi(t) | \mathcal{O}_i(t) | \psi(t)) = \langle \mathcal{O}(t) \rangle,$$

(A.2)

we see that

$$\langle A_T(x, t) \rangle = \frac{\hbar}{2V\omega_k \epsilon_0} \left( \epsilon(\mathbf{k}; \lambda) a_{\mathbf{k}\lambda}(t) e^{i\mathbf{kx} - i\omega_k t} + \epsilon^*(\mathbf{k}; \lambda) a^*_{{\mathbf{k}\lambda}}(t) e^{-i\mathbf{kx} + i\omega_k t} \right).$$

(A.3)

If we, in particular, consider initial states $|\psi(0)\rangle$ such that $\langle \psi(0) | a_{\mathbf{k}\lambda} | \psi(0) \rangle = 0$ for all $\mathbf{k}$, like quantum states with a fixed number of photons, we find that

$$\langle A_T(x, t) \rangle = \sum_{\mathbf{k}\lambda} \frac{i}{2V\omega_k \epsilon_0} \left( \epsilon(\mathbf{k}; \lambda) \int_0^t dt' e^{i\omega_k(t' - t) + i\mathbf{kx}} \epsilon^*(\mathbf{k}; \lambda) \cdot j^*(\mathbf{k}, t') \right)$$

$$- \epsilon^*(\mathbf{k}; \lambda) \int_0^t dt' e^{-i\omega_k(t' - t) - i\mathbf{kx}} \epsilon(\mathbf{k}; \lambda) \cdot j(\mathbf{k}, t')$$

$$= -\sum_{\mathbf{k}\lambda} \frac{1}{V\epsilon_0} e^{i\mathbf{kx}} \int_0^t dt' \frac{\sin(\omega_k(t' - t))}{\omega_k} \epsilon(\mathbf{k}; \lambda) \cdot \epsilon^*(\mathbf{k}; \lambda) \cdot j^*(\mathbf{k}, t'),$$

(A.4)

after a change $\mathbf{k} \rightarrow -\mathbf{k}$ in the last term above, using $j(-\mathbf{k}, t) = j^*(\mathbf{k}, t)$ as well as equation (4.12). The second time-derivative of this expression will then contain the following factor:

$$\sum_{\mathbf{k}\lambda} \frac{1}{V\epsilon_0} e^{i\mathbf{kx}} \epsilon(\mathbf{k}; \lambda) \cdot j^*(\mathbf{k}, t) = \sum_{\mathbf{k}} \frac{1}{V\epsilon_0} e^{i\mathbf{kx}} \left( j^*(\mathbf{k}, t) - \hat{k}(\mathbf{k} \cdot j(\mathbf{k}, t)) \right),$$

(A.5)

where $j^*_x(\mathbf{k}, t) = j_x(-\mathbf{k}, t) \equiv j_x(-\mathbf{k}, t) - \hat{k}(\mathbf{k} \cdot j(\mathbf{k}, t))$ corresponds to the Fourier-components of a transverse current $j_T(x, t)$ such that $\nabla \cdot j_T(x, t) = 0$, and where use have been made of equation (2.20). The transverse term obtained using equation (A.5) can therefore be written in the form:

$$\frac{1}{V\epsilon_0} \sum_{\mathbf{k}} e^{i\mathbf{kx}} j_x(-\mathbf{k}, t) = \frac{1}{V\epsilon_0} \frac{1}{\epsilon_0} \int d^3x' e^{-i\mathbf{kx'}} j_x(x', t) = \frac{1}{\epsilon_0} j_x(x, t),$$

(A.6)

where we make use of the fact that

$$\frac{1}{V} \sum_{\mathbf{k}} e^{i\mathbf{k}(x - x')} = \delta^{(3)}(x - x').$$

(A.7)

We have therefore reproduced the source-term in the wave-equation equation (4.13) in the main text and terms we have left out in the evaluation of $\partial^2 \langle A_T(x, t) / \partial t^2$ for $\langle \psi(0) | a_{\mathbf{k}\lambda} | \psi(0) \rangle = 0$ will satisfy the homogeneous wave-equation.
