Dear Editor

We are grateful to the critical response from the reviewer. We have added response to the 7 Comments from the reviewer. In the revised version the changes made in 2-7 are in yellow background.

We hope that the revised version can be published in SJG

On behalf of the authors

Jon Florholmen  
professor

Reviewer: 1

1. The English needs to be corrected/edited. There are several grammatical mistakes, especially on the singular/plural form of the subject/predicate.

Response: The English language has been improved in the revised manuscript by a competent native English person.

2. I am worried about the confounding factors in the immunological status of the subjects. Were all the immunological illnesses excluded? How "severe chronic disease" is defined on page 6, row 112.

Response: Severe chronic diseases were excluded including severe immunological diseases such as rheumatoid, Bechterew, SLE etc. The severe diseases were based diagnosis in the patients medical record and on well-documented and accepted international criteria. We fully agree with the critic and the content of severe disease is more detailed described in the revised version.

3. Are all the inclusion and exclusion criteria explained in the paper?

Response: We agree that the mandatory inclusion and exclusion criteria are suboptimal presented. In short, the logistics were as followed: there was a screening of patients performing a coloscopy and recruited were patients that fulfilled Rome II criteria for IBS diagnosis. Then the next step was the ordinary management of patients with IBS: exclusion of other GI diseases. This included as described, *blood tests, stool samples, breath tests, endoscopy, histological examination, X-ray, or ultrasound investigations to exclude organic disease or other malabsorption diseases including lactose intolerance*. These extra investigation were not mandatory except for blood test, and performed when only judged as actual by the clinician. Therefore, one exclusion criteria was other GI diseases. In addition as described *Patients with post-infectious IBS were excluded. If patients did meet Rome II criteria for diagnosis of IBS and other GI diseases and severe chronic disease were excluded, they were invited to participate in the study as the IBS group.* In the revised version standard screening laboratory test including transglutaminase was performed, The revised version is changed to a more optimal and readable describing inclusion and exclusion criteria.

4. The authors write that the individual diagnostic workup was not mandatory. What were the exclusion criteria? How could they be excluded if the laboratory analyses were not

1  
2  
3 mandatory? Why was the "individual diagnostic workup" done if it was not at all used in  
4 analyzing the results?

5 -Only fructose intolerance test was performed. What about other intolerances (like lactose)  
6 and allergies - again if the tests were not mandatory?  
7

8  
9 Response: The logistics are described and commented above, According to the question of  
10 food allergy and lactose intolerance. the patients were carefully asked for food allergy and  
11 lactose intolerance and were excluded if typical symptoms. In cases of uncertainty food  
12 allergy blood tests and lactose intolerance test were performed. In the revised version this is  
13 implemented  
14

15  
16 5. Dietary intake (content and timing) was not evaluated (e.g. fiber intake vs bloating). It  
17 could be a confounding factor.  
18

19 Response: The patients were told to use their ordinary food intake but a more defined diet  
20 intake including fiber content would definitely given more comprehensible data. If this lack  
21 represents a confounding factor and/or a causal factor is questionable. Anyhow, this is  
22 implemented in the Discussion of microbiota potential effect on our inflammation markers-  
23 see point 7.  
24  
25

26 6. FRD should be in the abbreviation list or explained in the text. It is a bit surprising that  
27 there were no mixed type of IBS.  
28

29 Response: FRD added both in the abbreviation list. As described in the text: *All IBS patients*  
30 *had a combination of diarrhea and constipation so subgrouping could not be performed*  
31  
32

33 7. The possible role of diet and intestinal microbiota on the inflammation markers could be  
34 shortly discussed.  
35  
36

37 Response: added in Discussion, last paragraph

3 45 **ABSTRACT**

4 46 **Background:** It has been proposed that irritable bowel syndrome (IBS) is as a low-grade  
5  
6  
7 47 mucosal inflammatory disease.

8  
9 48 **Objective:** To characterize the intestinal inflammatory profile in IBS patients with or without  
10  
11 49 fructose intolerance.

12  
13 50 **Design:** Patients referred to colonoscopy with IBS complaints were screened for participation.  
14  
15  
16 51 IBS patients diagnosed according to the Rome II criteria and with no organic gastrointestinal  
17  
18 52 disease were included in the study. One subgroup was patients included in a fructose-reduced  
19  
20 53 diet study for 2 months with effects based on VAS symptom scores. Healthy controls were  
21  
22 54 subjects under investigation of colorectal cancer screening with no IBS or other  
23  
24 55 gastrointestinal diseases. All patients included had normal histology from rectum. Mucosal  
25  
26 56 cytokines, chemokines and growth factors were measured by multiplex technology.

27  
28 57 **Results:** Of 27 inflammatory markers tested in the mucosal tissue, 13 were significantly  
29  
30 58 increased and none was significantly decreased in IBS as compared to controls. Significantly  
31  
32 59 increased were the proinflammatory cytokines tumor necrosis factor, the typical TH1 markers  
33  
34 60 IFN $\gamma$ , IL-1 $\beta$ , IL-2 and RANTES, the typical TH2 markers IL-5 and IL-9, the TH17 marker  
35  
36 61 IL-17, TNF, the pleiotropic IL-15, and the growth factors bFGF and GM-CSF. In IBS patients  
37  
38 62 with fructose intolerance only IL-5 was significantly increased compared to patients without  
39  
40 63 fructose intolerance.

41  
42 64 **Conclusion:** A dysregulated mucosal inflammatory profile with an increased level of TH1,  
43  
44 65 TH2 and TH17 markers, and growth factors were observed in bowel mucosa in of IBS  
45  
46 66 patients when compared to healthy controls.

## 1. Introduction

Irritable bowel syndrome (IBS) is characterized as a functional disease as there are no well-documented causal pathophysiological mechanisms. Typically, in IBS there is a hypersensitivity with low response threshold to various external stimuli, first documented by Ritchie J in 1973 [1]. This hypersensitivity of afferent neurons is activated by stimuli such as distension of hollow organs and chemical mediators such as proinflammatory and lipotoxic molecules (for review, see reference [2]). The underlying mechanisms behind visceral hypersensitivity in IBS is unknown, but the most referred hypothesis is that the visceral hypersensitivity in IBS is caused by an aberrant neuroimmune interaction (for review, see [2-7]).

One of the first reports suggesting IBS as a low-grade mucosal inflammatory disease was by Collins in 1992 [8], but this hypothesis is still controversial [9]. Two features support this hypothesis: IBS is frequently seen both after a gastrointestinal infection [10] and in inflammatory bowel disease in remission [11]. However, the documentation of visceral hypersensitivity as a neuroimmune dysregulation in IBS is poor. At the level of mucosal immune cells, several reports describing increased number of T lymphocytes [12-14], mast cells [15,16], and degranulated mast cells [14,17]. Somewhat contradictory, decreased levels of T cells and mast cells have been reported [18] in post infectious and classical IBS. Moreover, various results have been reported for cytokines and chemokines at mucosal level: increased transcript levels of IL-1 $\beta$  [19] has been reported, decreased transcript levels were observed for IL-10 [20,21] and for the chemokines IL-8, CXCL-9 and MCP1 [22], an imbalance between TH1 and TH2 cytokines was observed [23], whereas no changes were observed for the proinflammatory TNF alpha, IL-6 and IL-beta [22]. Finally, in contrast to these reports, no significant differences between classical, non-postinfectious IBS and healthy control were found neither at the mucosal levels of immune cells nor at transcript levels

1  
2  
3 95 [24,25]. Taken together, there are contradictory reports concerning the type of immune  
4  
5 96 dysregulation involved if IBS can be explained as a low-grade inflammatory bowel disease.  
6  
7

8 97 The aim of this study was to identify the inflammatory profile of various relevant  
9  
10 98 cytokines, chemokines and growth factors in colon biopsies from patients with IBS, including  
11  
12 99 the subgroup with self-reported fructose intolerance, compared to healthy controls.

## 2. Materials and methods

### 2.1. Subject groups

The patients were recruited from three cohorts: from patients referred to colonoscopy due to IBS symptoms, from the FINN study (Fructose malabsorption In North Norway, [25] 26, Berg 2013), and patients in colorectal cancer screening. The recruited patients were first interviewed for a complete medical record to ensure they fulfilled Rome II criteria for IBS diagnosis. The inclusion criteria were patients who fulfilled Rome II criteria and were willing to participate. They then underwent an individual diagnostic workup including, but not mandatory, blood tests, stool samples, breath tests, endoscopy, histological examination, X-ray, or ultrasound investigations to exclude organic disease or other malabsorption diseases including lactose intolerance and food allergy. A standard screening laboratory test including test for celiac disease was performed. According to the question of food allergy and lactose intolerance, the patient were carefully asked for food allergy and lactose intolerance and were excluded if typical symptoms. In some cases with uncertainty, food allergy blood tests and lactose breath test were performed. The exclusion criteria were patients with other gastrointestinal diseases, including post-infectious IBS, use of laxatives due to constipation, patients with severe medical disorders such as diabetes mellitus, cancer, severe cerebral, lung or heart diseases and finally patients with severe immunological diseases such as rheumatoid arthritis, SLE etc. A subgroup of the IBS patients were further included in the FINN study. They performed a diagnostic test for self-reported dietary fructose intolerance (12-week fructose reduced diet (FRD) followed by 1 week high-fructose provocation test) [27]. Finally, patients with no IBS symptoms according to Rome II criteria represented the healthy control group. All patients performed colonoscopy, 20 biopsies were obtained from rectum and stored at – 70°C until analysis. Biopsies were also obtained for ordinary histological examinations (haematoxylin and eosin staining). The IBS group and the healthy control group were

1  
2  
3 127 included in the study if no endoscopic nor histological sign of pathology, and no other  
4  
5 128 gastrointestinal disease including post-infectious IBS and severe medical disorders. Moreover,  
6  
7 129 in all subjects, VAS registrations for pain and bloating (0-100 mm, 0 mm for no symptoms  
8  
9 130 and 100 mm for maximal symptom score) were performed, and the number of stools and  
10  
11 131 registration of stool quality on a scale from 1-7 (Bristol scale [27]).  
12  
13  
14  
15 132

## 17 133 2.2. *Analyses of cytokines, chemokines and growth factors*

19 134 The mucosal profile of various relevant cytokines, chemokines and growth factors were  
20  
21 135 determined by multiplex technology. Homogenization of tissue was performed with the  
22  
23 136 following protocol: A mix of 495  $\mu$ L CytoBuster Protein Extraction Reagent (Novagen, San  
24  
25 137 Diego, CA) and 5  $\mu$ L Protease Inhibitor cocktail set 1 (Calbiochem, Darmstadt, Germany)  
26  
27 138 was added to 50 mg of tissue sample and homogenized with Xiril Dispomix. After  
28  
29 139 completion, the samples were incubated for five minutes on ice and thereafter centrifuged at  
30  
31 140 2,500 x g for 20 minutes at 4 °C. The supernatants were transferred to Nunc tubes and stored  
32  
33 141 at -70°C. The samples were analyzed using a multiplex cytokine assay (Bio-Plex Human  
34  
35 142 Cytokine 27-Plex Panel; Bio-Rad Laboratories Inc., Hercules, CA, USA) containing the  
36  
37 143 following interleukins, chemokines and growth factors: Interleukin (IL)-1 $\beta$ , IL-1 receptor  
38  
39 144 antagonist (IL1-ra), IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-9, IL-10, IL-12 (p70), IL-13, IL-15,  
40  
41 145 IL-17, eotaxin, basic fibroblast growth factor (bFGF), granulocyte-colony stimulating factor  
42  
43 146 (G-CSF), granulocyte macrophage colony stimulating factor (GM-CSF), interferon (IFN)- $\gamma$ ,  
44  
45 147 interferon-inducible protein (IP-10), monocyte chemotactic protein (MCP-1), macrophage  
46  
47 148 inflammatory protein (MIP)-1 $\alpha$ , MIP-1 $\beta$ , platelet derived growth factor-BB (PDGF-BB),  
48  
49 149 regulated upon activation T cell expressed and secreted (RANTES), tumor necrosis factor  
50  
51 150 (TNF), and vascular endothelial growth factor (VEGF). The samples were analyzed on a  
52  
53 151 Multiplex Analyzer (Bio-Rad Laboratories) according to instructions from the manufacturer.  
54  
55  
56  
57  
58  
59  
60

152

### 2.3. *Ethics and registrations*

The study was approved by the Regional Committee of Medical Ethics North Norway (ID:

136/2006), and the study was registered in [clinicaltrials.gov](https://clinicaltrials.gov) NCT00555191

156

157

### 2.4. *Statistical analysis*

Baseline characteristics and individual mediator measurements were explored using parametric tests; in most cases it was necessary to perform a logarithmic transformation to obtain a normal distribution. Chi-square test was used for contingency tables. A principal component analysis was performed on the mediator readings from all subject groups. Further details in the result section.

164

## 3. Results

### 3.1. Subject groups

A total of 42 IBS patients were included, 14 patients performing **fructose reduced diet (FRD)** where 8 patients had fructose intolerance based on the criteria of effect of fructose restricted diet (< 2 g fructose/meal) and positive provocation test on fructose-rich meals [27] and 6 patients had no fructose intolerance. All IBS patients had a combination of diarrhea and constipation so subgrouping could not be performed. The demographics are shown in table 1.

172

### 3.2. *Mucosal intestinal inflammatory profiles in IBS patients versus healthy controls*

Of the 27 mediators measured, 13 was significantly ( $p < 0.05$ ) increased and none were decreased in the IBS patients compared to controls (Table 2).

### 3.3. *Cytokines*

176

1  
2  
3 177 Most of the proinflammatory cytokines were increased at significant levels such as the TH1  
4  
5 178 cytokines  $\text{INF}\gamma$ , IL-1 $\beta$ , IL-2, the pleiotropic IL-15, the TH17 cytokine IL-17, TNF, but not  
6  
7 179 IL-6, IL-7 or IL-8. The TH2 cytokines IL-4 and IL-9, but not IL-5, was significantly increased  
8  
9 180 compared to the healthy control group (table 2).

#### 12 181 3.4. Chemokines

14 182 Of the chemokines analyzed, only RANTES and Eotaxin were significantly increased when  
15  
16 183 compared to the control group (table 2).

#### 19 184 3.5. Growth factors

21 185 Of the various growth factors analyzed, bFGF, PDGFBB, and GM-CSF were significantly  
22  
23 186 increased, but not the other growth factors when compared to the control group (table 2).

#### 28 188 3.6. Intestinal immune profile in subgroups of IBS

30 189 IL-5 was significantly increased in IBS patients with self-reported fructose intolerance only  
31  
32 190 (0.4 pg/mL [0.2 – 0.6] n=6) compared to patients without fructose intolerance (0.1 pg/mL [0.0  
33  
34 191 – 0.3] n=8) P= 0.02 (data not shown for the rest).

#### 40 193 3.7. Principal component analysis

42 194 Principal component analysis of the dataset extracted 3 components with a cumulative  
43  
44 195 explained variance of 55% (KMO 0.69; Bartlett's test of sphericity Chi-square = 1835; df =  
45  
46 196 351; P = 4.9 E-199). The rotated solution showed that PC1 (30 % variance explained) had  
47  
48 197 highest factor loadings on the mediators TNF, IL-4,  $\text{IFN}\gamma$ , IL-17 and IL-2 corresponding to a  
49  
50 198 pro-inflammatory cytokine axis. PC2 (13 % variance explained) had highest factor loadings  
51  
52 199 on IL-8, IL-6, IL-9, FGF basic, and MIP-1 $\alpha$  corresponding to a pro-inflammatory chemokine  
53  
54 200 axis. Finally, PC3 (11 % variance explained) had highest loadings on VEGF, IL-10, IL-12  
55  
56 201 (p70), IL-7, and IL-5 the direction of which is not entirely clear. Figure 1 shows factor  
57  
58  
59  
60

1  
2  
3 202 loadings of PC1 and PC2 for the individual observations in the study groups. Many IBS  
4  
5 203 subjects are located among the normal controls. However, some degree of immune activation  
6  
7 204 may exist in subgroups of IBS.

#### 4. Discussion

In this study, we have found increased mucosal levels of proinflammatory TH1 cytokines IFN- $\gamma$ , IL-1b, IL-2; the TH1 chemokine RANTES, the TH 17 cytokine IL-17 cytokine, the TH2 and allergy -associated cytokines IL-5, TNF and IL-9; the growth factors FGF basic and GM-CSF, when compared to healthy control without IBS symptoms. Our study indicates that in IBS with no sign of infiltrating leucocytes at HE histology examinations represents a disease of immune dysregulation whereas an apparent minor immune dysregulation may be due to the fructose intolerance.

The mucosal levels of some of the mucosal cytokines TH1, TH2 and TH17 were significantly increased in IBS compared to the healthy control group. These cytokines which is generally increased in IBD, although at much higher levels, has to some extent been studied in IBS [28,29]. Thus, various differences to mucosal levels in healthy controls have been reported in some publications [19,23,30] but not in others [21,24,25]. Also of interest to note was the mucosal TNF as one of the main mediators of IBD [28], was increased in this study but not in other studies [20,22]. This may be due to methodological differences, especially considering the low-level increase registered. The TNF-alpha G/A polymorphism at position 308 has been observed in IBS patients [31] and may have pathophysiological role in IBS.

The two TH2 cytokines IL-5 and IL-9 were increased compared to the healthy control group. Both cytokines secreted from mast cells that has been proposed to be one of the main mediators of hypersensitivity in IBS [32]. Our IL-5 and IL9 data are in agreement with previous reports in IBS [33,34]. Therefore, all these data taken together indicate that in IBS a mucosal TH2 dysregulation exists, which mediates a low-grade inflammation with activation of inflammatory cells such as mast cells [3,32].

The mucosal level of the TH1 chemokine RANTES and eotaxin was significantly increased in IBS. First, the eotaxin result fits well with the documentation of mast cell

1  
2  
3 232 activation in IBS [16] and the mast cell activation of eotaxin [35]. Moreover, our data agrees  
4  
5 233 with our findings of increased levels of the TH1 cytokines and TNF as cytokines with strong  
6  
7  
8 234 effect on activation of chemotaxis. In another report, CXCL-9 and MCP1 were even lower in  
9  
10 235 IBS than in the healthy controls [22]. These discrepancies are hard to explain. The  
11  
12 236 chemokines are responsible for the leukocyte migration by creating a chemical gradient from  
13  
14 237 the vascular endothelium to the infected cells and by selective expressions of different  
15  
16  
17 238 chemokine receptors on the leukocytes [36]. It is interesting to speculate that a lack of a more  
18  
19 239 complete and global chemokine response may be one explanation of the lack of a tissue  
20  
21 240 invasion of leucocytes measured by conventional diagnostic procedures.

23  
24 241 Of the various growth factors measured, there were significant increases in the growth  
25  
26 242 factors bFGF, PDGFBB and GM-CSF. As far as we know there are no previous reports of  
27  
28 243 these two mucosal growth factors in IBS. Other growth factors such as neural growth factor  
29  
30 244 has been shown to be overexpressed in intestinal mucosa in IBS [37]. In general, growth  
31  
32 245 factors play a role to maintain the mucosa integrity [38] are proposed to have anti-  
33  
34  
35 246 inflammatory effects. In chronic inflammation such as in IBD, these mediators play a role in  
36  
37 247 the mucosal healing.

38  
39  
40 248 In IBS patients with self-reported fructose intolerance, only IL-5 was significantly  
41  
42 249 increased compared to IBS patients without fructose intolerance indicating a possible allergy-  
43  
44 250 like mechanism. The pathophysiological mechanisms behind this condition is unknown, but it  
45  
46 251 has been proposed to be due to reduced intestinal absorption capacity of fructose [39].  
47  
48  
49 252 Whether an allergic mechanism could be involved, has to be further investigated.

50  
51 253 In general, IBS is most likely a heterogeneous disease where the main proposed  
52  
53 254 contributing pathophysiological factors are neuroendocrine abnormalities, low grade  
54  
55 255 inflammation, failure of the gut barrier, increased fecal bile content, abnormal visceral  
56  
57  
58 256 hypersensitivity and psychosocial stress. Moreover, stress as a causal factor of immune  
59  
60

1  
2  
3 257 dysregulation in the gut has been known for long in animals [40] and in humans (for review,  
4  
5 258 see [41]. The heterogeneity is supported by the various contradictory reports concerning the  
6  
7 259 mucosal immunophenotype between our and other reports (for review, see [4,7,42,43]. The  
8  
9 260 pathophysiological mechanism behind IBS can either be abnormal interactions between  
10  
11 261 neurons/nerves and immune cells [43], also referred to as the “neuroimmune” synapse [6].  
12  
13 262 Moreover, though many of the IBS subjects in the present study show a pro-inflammatory  
14  
15 263 tendency, a substantial part of the IBS subjects falls within the “normal control” sphere  
16  
17 264 (figure 1), which underlines the impression that IBS is a disorder of heterogenic pathogenesis.  
18  
19 265 Finally, we should be aware that the suggested immunological disturbances in IBS is still  
20  
21 266 least controversial and described by some as a possible myth [44].  
22  
23  
24

25  
26 267 The strength of this study is the broad mucosal characterization of cytokines, chemokines  
27  
28 268 and growth factors that would be potentially involved in IBS as an immunological active  
29  
30 269 disease. The weakness of the study that should initiate further studies is that whole biopsy  
31  
32 270 extracts is relatively crude. A mucosal immunologic characterization at cellular level would  
33  
34 271 give more comprehensive data. Moreover, IBS is most likely a heterogeneous disease  
35  
36 272 concerning the potential etiological factors and the various clinical phenotypes. Therefore,  
37  
38 273 further studies are needed focusing on subgrouping defined by subgroup phenotypes of IBD,  
39  
40 274 as well as precipitating factors such as infection, stress and antibiotics. Moreover, potentially,  
41  
42 275 the inflammatory biomarkers could be explained by changes in the fecal microbiota, and  
43  
44 276 microbiotic phenotypes related to diet including fiber intake [45,46]. This awaits further  
45  
46 277 studies.  
47  
48  
49  
50

51 278  
52  
53 279 In conclusion, a dysregulated mucosal immune profile with a mixed TH1, TH2, TH17 and  
54  
55 280 growth factor profile is observed in IBS patients when compared to healthy control. This  
56  
57 281 indicates that IBS is a low-grade inflammatory bowel disease with an apparent incomplete  
58  
59  
60

1  
2  
3 282 chemotactic stimulus that may preclude recruitment of leucocytes from the general  
4  
5 283 circulation.

2  
3 45 **ABSTRACT**

4 46 **Background:** It has been proposed that irritable bowel syndrome (IBS) is as a low-grade  
5  
6  
7 47 mucosal inflammatory disease.

8  
9 48 **Objective:** To characterize the intestinal inflammatory profile in IBS patients with or without  
10  
11 49 fructose intolerance.

12  
13 50 **Design:** Patients referred to colonoscopy with IBS complaints were screened for participation.  
14  
15  
16 51 IBS patients diagnosed according to the Rome II criteria and with no organic gastrointestinal  
17  
18 52 disease were included in the study. One subgroup was patients included in a fructose-reduced  
19  
20 53 diet study for 2 months with effects based on VAS symptom scores. Healthy controls were  
21  
22 54 subjects under investigation of colorectal cancer screening with no IBS or other  
23  
24 55 gastrointestinal diseases. All patients included had normal histology from rectum. Mucosal  
25  
26 56 cytokines, chemokines and growth factors were measured by multiplex technology.

27  
28 57 **Results:** Of 27 inflammatory markers tested in the mucosal tissue, 13 were significantly  
29  
30 58 increased and none was significantly decreased in IBS as compared to controls. Significantly  
31  
32 59 increased were the proinflammatory cytokines tumor necrosis factor, the typical TH1 markers  
33  
34 60 IFN $\gamma$ , IL-1 $\beta$ , IL-2 and RANTES, the typical TH2 markers IL-5 and IL-9, the TH17 marker  
35  
36 61 IL-17, TNF, the pleiotropic IL-15, and the growth factors bFGF and GM-CSF. In IBS patients  
37  
38 62 with fructose intolerance only IL-5 was significantly increased compared to patients without  
39  
40 63 fructose intolerance.

41  
42 64 **Conclusion:** A dysregulated mucosal inflammatory profile with an increased level of TH1,  
43  
44 65 TH2 and TH17 markers, and growth factors were observed in bowel mucosa in of IBS  
45  
46 66 patients when compared to healthy controls.

## 1. Introduction

Irritable bowel syndrome (IBS) is characterized as a functional disease as there are no well-documented causal pathophysiological mechanisms. Typically, in IBS there is a hypersensitivity with low response threshold to various external stimuli, first documented by Ritchie J in 1973 [1]. This hypersensitivity of afferent neurons is activated by stimuli such as distension of hollow organs and chemical mediators such as proinflammatory and lipotoxic molecules (for review, see reference [2]). The underlying mechanisms behind visceral hypersensitivity in IBS is unknown, but the most referred hypothesis is that the visceral hypersensitivity in IBS is caused by an aberrant neuroimmune interaction (for review, see [2-7]).

One of the first reports suggesting IBS as a low-grade mucosal inflammatory disease was by Collins in 1992 [8], but this hypothesis is still controversial [9]. Two features support this hypothesis: IBS is frequently seen both after a gastrointestinal infection [10] and in inflammatory bowel disease in remission [11]. However, the documentation of visceral hypersensitivity as a neuroimmune dysregulation in IBS is poor. At the level of mucosal immune cells, several reports describing increased number of T lymphocytes [12-14], mast cells [15,16], and degranulated mast cells [14,17]. Somewhat contradictory, decreased levels of T cells and mast cells have been reported [18] in post infectious and classical IBS. Moreover, various results have been reported for cytokines and chemokines at mucosal level: increased transcript levels of IL-1 $\beta$  [19] has been reported, decreased transcript levels were observed for IL-10 [20,21] and for the chemokines IL-8, CXCL-9 and MCP1 [22], an imbalance between TH1 and TH2 cytokines was observed [23], whereas no changes were observed for the proinflammatory TNF alpha, IL-6 and IL-beta [22]. Finally, in contrast to these reports, no significant differences between classical, non-postinfectious IBS and healthy control were found neither at the mucosal levels of immune cells nor at transcript levels

1  
2  
3 95 [24,25]. Taken together, there are contradictory reports concerning the type of immune  
4  
5 96 dysregulation involved if IBS can be explained as a low-grade inflammatory bowel disease.  
6

7  
8 97 The aim of this study was to identify the inflammatory profile of various relevant  
9  
10 98 cytokines, chemokines and growth factors in colon biopsies from patients with IBS, including  
11  
12 99 the subgroup with self-reported fructose intolerance, compared to healthy controls.

## 2. Materials and methods

### 2.1. Subject groups

The patients were recruited from three cohorts: from patients referred to colonoscopy due to IBS symptoms, from the FINN study (Fructose malabsorption In North Norway, [25] 26, Berg 2013), and patients in colorectal cancer screening. The recruited patients were first interviewed for a complete medical record to ensure they fulfilled Rome II criteria for IBS diagnosis. The inclusion criteria were patients who fulfilled Rome II criteria and were willing to participate. They then underwent an individual diagnostic workup including, but not mandatory, blood tests, stool samples, breath tests, endoscopy, histological examination, X-ray, or ultrasound investigations to exclude organic disease or other malabsorption diseases including lactose intolerance and food allergy. A standard screening laboratory test including test for celiac disease was performed. According to the question of food allergy and lactose intolerance, the patient were carefully asked for food allergy and lactose intolerance and were excluded if typical symptoms. In some cases with uncertainty, food allergy blood tests and lactose breath test were performed. The exclusion criteria were patients with other gastrointestinal diseases, including post-infectious IBS, use of laxatives due to constipation, patients with severe medical disorders such as diabetes mellitus, cancer, severe cerebral, lung or heart diseases and finally patients with severe immunological diseases such as rheumatoid arthritis, SLE etc. A subgroup of the IBS patients were further included in the FINN study. They performed a diagnostic test for self-reported dietary fructose intolerance (12-week fructose reduced diet (FRD) followed by 1 week high-fructose provocation test) [27]. Finally, patients with no IBS symptoms according to Rome II criteria represented the healthy control group. All patients performed colonoscopy, 20 biopsies were obtained from rectum and stored at – 70°C until analysis. Biopsies were also obtained for ordinary histological examinations (haematoxylin and eosin staining). The IBS group and the healthy control group were

1  
2  
3 127 included in the study if no endoscopic nor histological sign of pathology, and no other  
4  
5 128 gastrointestinal disease including post-infectious IBS and severe medical disorders. Moreover,  
6  
7 129 in all subjects, VAS registrations for pain and bloating (0-100 mm, 0 mm for no symptoms  
8  
9 130 and 100 mm for maximal symptom score) were performed, and the number of stools and  
10  
11 131 registration of stool quality on a scale from 1-7 (Bristol scale [27]).  
12  
13  
14  
15 132

## 17 133 2.2. *Analyses of cytokines, chemokines and growth factors*

19 134 The mucosal profile of various relevant cytokines, chemokines and growth factors were  
20  
21 135 determined by multiplex technology. Homogenization of tissue was performed with the  
22  
23 136 following protocol: A mix of 495  $\mu$ L CytoBuster Protein Extraction Reagent (Novagen, San  
24  
25 137 Diego, CA) and 5  $\mu$ L Protease Inhibitor cocktail set 1 (Calbiochem, Darmstadt, Germany)  
26  
27 138 was added to 50 mg of tissue sample and homogenized with Xiril Dispomix. After  
28  
29 139 completion, the samples were incubated for five minutes on ice and thereafter centrifuged at  
30  
31 140 2,500 x g for 20 minutes at 4 °C. The supernatants were transferred to Nunc tubes and stored  
32  
33 141 at -70°C. The samples were analyzed using a multiplex cytokine assay (Bio-Plex Human  
34  
35 142 Cytokine 27-Plex Panel; Bio-Rad Laboratories Inc., Hercules, CA, USA) containing the  
36  
37 143 following interleukins, chemokines and growth factors: Interleukin (IL)-1 $\beta$ , IL-1 receptor  
38  
39 144 antagonist (IL1-ra), IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-9, IL-10, IL-12 (p70), IL-13, IL-15,  
40  
41 145 IL-17, eotaxin, basic fibroblast growth factor (bFGF), granulocyte-colony stimulating factor  
42  
43 146 (G-CSF), granulocyte macrophage colony stimulating factor (GM-CSF), interferon (IFN)- $\gamma$ ,  
44  
45 147 interferon-inducible protein (IP-10), monocyte chemotactic protein (MCP-1), macrophage  
46  
47 148 inflammatory protein (MIP)-1 $\alpha$ , MIP-1 $\beta$ , platelet derived growth factor-BB (PDGF-BB),  
48  
49 149 regulated upon activation T cell expressed and secreted (RANTES), tumor necrosis factor  
50  
51 150 (TNF), and vascular endothelial growth factor (VEGF). The samples were analyzed on a  
52  
53 151 Multiplex Analyzer (Bio-Rad Laboratories) according to instructions from the manufacturer.  
54  
55  
56  
57  
58  
59  
60

152

### 2.3. *Ethics and registrations*

The study was approved by the Regional Committee of Medical Ethics North Norway (ID:

136/2006), and the study was registered in [clinicaltrials.gov](https://clinicaltrials.gov) NCT00555191

156

157

### 2.4. *Statistical analysis*

Baseline characteristics and individual mediator measurements were explored using parametric tests; in most cases it was necessary to perform a logarithmic transformation to obtain a normal distribution. Chi-square test was used for contingency tables. A principal component analysis was performed on the mediator readings from all subject groups. Further details in the result section.

164

## 3. Results

### 3.1. Subject groups

A total of 42 IBS patients were included, 14 patients performing **fructose reduced diet (FRD)** where 8 patients had fructose intolerance based on the criteria of effect of fructose restricted diet (< 2 g fructose/meal) and positive provocation test on fructose-rich meals [27] and 6 patients had no fructose intolerance. All IBS patients had a combination of diarrhea and constipation so subgrouping could not be performed. The demographics are shown in table 1.

172

### 3.2. *Mucosal intestinal inflammatory profiles in IBS patients versus healthy controls*

Of the 27 mediators measured, 13 was significantly ( $p < 0.05$ ) increased and none were decreased in the IBS patients compared to controls (Table 2).

### 3.3. *Cytokines*

176

1  
2  
3 177 Most of the proinflammatory cytokines were increased at significant levels such as the TH1  
4  
5 178 cytokines  $\text{INF}\gamma$ , IL-1 $\beta$ , IL-2, the pleiotropic IL-15, the TH17 cytokine IL-17, TNF, but not  
6  
7 179 IL-6, IL-7 or IL-8. The TH2 cytokines IL-4 and IL-9, but not IL-5, was significantly increased  
8  
9 180 compared to the healthy control group (table 2).

#### 12 181 3.4. Chemokines

14 182 Of the chemokines analyzed, only RANTES and Eotaxin were significantly increased when  
15  
16 183 compared to the control group (table 2).

#### 19 184 3.5. Growth factors

21 185 Of the various growth factors analyzed, bFGF, PDGFBB, and GM-CSF were significantly  
22  
23 186 increased, but not the other growth factors when compared to the control group (table 2).

#### 28 188 3.6. Intestinal immune profile in subgroups of IBS

30 189 IL-5 was significantly increased in IBS patients with self-reported fructose intolerance only  
31  
32 190 (0.4 pg/mL [0.2 – 0.6] n=6) compared to patients without fructose intolerance (0.1 pg/mL [0.0  
33  
34 191 – 0.3] n=8) P= 0.02 (data not shown for the rest).

#### 40 193 3.7. Principal component analysis

42 194 Principal component analysis of the dataset extracted 3 components with a cumulative  
43  
44 195 explained variance of 55% (KMO 0.69; Bartlett's test of sphericity Chi-square = 1835; df =  
45  
46 196 351; P = 4.9 E-199). The rotated solution showed that PC1 (30 % variance explained) had  
47  
48 197 highest factor loadings on the mediators TNF, IL-4,  $\text{IFN}\gamma$ , IL-17 and IL-2 corresponding to a  
49  
50 198 pro-inflammatory cytokine axis. PC2 (13 % variance explained) had highest factor loadings  
51  
52 199 on IL-8, IL-6, IL-9, FGF basic, and MIP-1 $\alpha$  corresponding to a pro-inflammatory chemokine  
53  
54 200 axis. Finally, PC3 (11 % variance explained) had highest loadings on VEGF, IL-10, IL-12  
55  
56 201 (p70), IL-7, and IL-5 the direction of which is not entirely clear. Figure 1 shows factor

#### 4. Discussion

In this study, we have found increased mucosal levels of proinflammatory TH1 cytokines IFN- $\gamma$ , IL-1b, IL-2; the TH1 chemokine RANTES, the TH 17 cytokine IL-17 cytokine, the TH2 and allergy -associated cytokines IL-5, TNF and IL-9; the growth factors FGF basic and GM-CSF, when compared to healthy control without IBS symptoms. Our study indicates that in IBS with no sign of infiltrating leucocytes at HE histology examinations represents a disease of immune dysregulation whereas an apparent minor immune dysregulation may be due to the fructose intolerance.

The mucosal levels of some of the mucosal cytokines TH1, TH2 and TH17 were significantly increased in IBS compared to the healthy control group. These cytokines which is generally increased in IBD, although at much higher levels, has to some extent been studied in IBS [28,29]. Thus, various differences to mucosal levels in healthy controls have been reported in some publications [19,23,30] but not in others [21,24,25]. Also of interest to note was the mucosal TNF as one of the main mediators of IBD [28], was increased in this study but not in other studies [20,22]. This may be due to methodological differences, especially considering the low-level increase registered. The TNF-alpha G/A polymorphism at position 308 has been observed in IBS patients [31] and may have pathophysiological role in IBS.

The two TH2 cytokines IL-5 and IL-9 were increased compared to the healthy control group. Both cytokines secreted from mast cells that has been proposed to be one of the main mediators of hypersensitivity in IBS [32]. Our IL-5 and IL9 data are in agreement with previous reports in IBS [33,34]. Therefore, all these data taken together indicate that in IBS a mucosal TH2 dysregulation exists, which mediates a low-grade inflammation with activation of inflammatory cells such as mast cells [3,32].

The mucosal level of the TH1 chemokine RANTES and eotaxin was significantly increased in IBS. First, the eotaxin result fits well with the documentation of mast cell

1  
2  
3 232 activation in IBS [16] and the mast cell activation of eotaxin [35]. Moreover, our data agrees  
4  
5 233 with our findings of increased levels of the TH1 cytokines and TNF as cytokines with strong  
6  
7 234 effect on activation of chemotaxis. In another report, CXCL-9 and MCP1 were even lower in  
8  
9 235 IBS than in the healthy controls [22]. These discrepancies are hard to explain. The  
10  
11 236 chemokines are responsible for the leukocyte migration by creating a chemical gradient from  
12  
13 237 the vascular endothelium to the infected cells and by selective expressions of different  
14  
15 238 chemokine receptors on the leukocytes [36]. It is interesting to speculate that a lack of a more  
16  
17 239 complete and global chemokine response may be one explanation of the lack of a tissue  
18  
19 240 invasion of leucocytes measured by conventional diagnostic procedures.  
20  
21  
22

23  
24 241 Of the various growth factors measured, there were significant increases in the growth  
25  
26 242 factors bFGF, PDGFBB and GM-CSF. As far as we know there are no previous reports of  
27  
28 243 these two mucosal growth factors in IBS. Other growth factors such as neural growth factor  
29  
30 244 has been shown to be overexpressed in intestinal mucosa in IBS [37]. In general, growth  
31  
32 245 factors play a role to maintain the mucosa integrity [38] are proposed to have anti-  
33  
34 246 inflammatory effects. In chronic inflammation such as in IBD, these mediators play a role in  
35  
36 247 the mucosal healing.  
37  
38  
39

40 248 In IBS patients with self-reported fructose intolerance, only IL-5 was significantly  
41  
42 249 increased compared to IBS patients without fructose intolerance indicating a possible allergy-  
43  
44 250 like mechanism. The pathophysiological mechanisms behind this condition is unknown, but it  
45  
46 251 has been proposed to be due to reduced intestinal absorption capacity of fructose [39].  
47  
48 252 Whether an allergic mechanism could be involved, has to be further investigated.  
49  
50

51 253 In general, IBS is most likely a heterogeneous disease where the main proposed  
52  
53 254 contributing pathophysiological factors are neuroendocrine abnormalities, low grade  
54  
55 255 inflammation, failure of the gut barrier, increased fecal bile content, abnormal visceral  
56  
57 256 hypersensitivity and psychosocial stress. Moreover, stress as a causal factor of immune  
58  
59  
60

1  
2  
3 257 dysregulation in the gut has been known for long in animals [40] and in humans (for review,  
4  
5 258 see [41]. The heterogeneity is supported by the various contradictory reports concerning the  
6  
7 259 mucosal immunophenotype between our and other reports (for review, see [4,7,42,43]. The  
8  
9 260 pathophysiological mechanism behind IBS can either be abnormal interactions between  
10  
11 261 neurons/nerves and immune cells [43], also referred to as the “neuroimmune” synapse [6].  
12  
13 262 Moreover, though many of the IBS subjects in the present study show a pro-inflammatory  
14  
15 263 tendency, a substantial part of the IBS subjects falls within the “normal control” sphere  
16  
17 264 (figure 1), which underlines the impression that IBS is a disorder of heterogenic pathogenesis.  
18  
19 265 Finally, we should be aware that the suggested immunological disturbances in IBS is still  
20  
21 266 least controversial and described by some as a possible myth [44].  
22  
23  
24

25  
26 267 The strength of this study is the broad mucosal characterization of cytokines, chemokines  
27  
28 268 and growth factors that would be potentially involved in IBS as an immunological active  
29  
30 269 disease. The weakness of the study that should initiate further studies is that whole biopsy  
31  
32 270 extracts is relatively crude. A mucosal immunologic characterization at cellular level would  
33  
34 271 give more comprehensive data. Moreover, IBS is most likely a heterogeneous disease  
35  
36 272 concerning the potential etiological factors and the various clinical phenotypes. Therefore,  
37  
38 273 further studies are needed focusing on subgrouping defined by subgroup phenotypes of IBD,  
39  
40 274 as well as precipitating factors such as infection, stress and antibiotics. Moreover, potentially,  
41  
42 275 the inflammatory biomarkers could be explained by changes in the fecal microbiota, and  
43  
44 276 microbiotic phenotypes related to diet including fiber intake [45,46]. This awaits further  
45  
46 277 studies.  
47  
48  
49  
50

51 278  
52  
53 279 In conclusion, a dysregulated mucosal immune profile with a mixed TH1, TH2, TH17 and  
54  
55 280 growth factor profile is observed in IBS patients when compared to healthy control. This  
56  
57 281 indicates that IBS is a low-grade inflammatory bowel disease with an apparent incomplete  
58  
59  
60

1  
2  
3 282 chemotactic stimulus that may preclude recruitment of leucocytes from the general  
4  
5 283 circulation.

426 **Table 1**

427 Demographic and baseline variables for patients included.

	IBS-All	IBS-FT	IBS-FI	Controls	P
	N=42	n=6	n=8	N=20	
Age (median [range])	48.5	50 [40 72]	48 [25 62]	59 [35 79]	Ns
Female per cent	68 %	63 %	100 %	35 %	0.019#
Abdominal pain/discomfort (mm)	55.2	61	50	0	Ns*
Bloating (mm)	56	63	51	0	Ns*
Stool frequency (median [range])	1.8	1.6	1.7	1.0	Ns*
Boston scale stool consistency (mean [range])	4,6	5.2	3.9	4.0	Ns*

428 FI: Fructose intolerance. FT: fructose tolerance. IBS: Irritable bowel syndrome. # Controls vs

429 IBS groups; \* IBS subgroups compared.

431 Table 2. Mucosal levels of cytokines, chemokines and growth factors in patients with IBS and  
 432 in healthy controls.

Mediator	IBS (N = 42)	Normal control (N = 20)	P
IFN $\gamma$	18 (16 – 20)	14 (12 – 17)	0.010
IL-1 $\beta$	6.7 (5.6 – 7.9)	4.1 (3.1 – 5.5)	0.004
IL-1RA	1299 (1012 – 1668)	818 (533 – 1254)	0.057
IL-2	0.64 (0.58 – 0.71)	0.39 (0.35 – 0.44)	<0.0005
IL-4	0.91 (0.79 – 1.04)	0.71 (0.62 – 0.82)	0.032
IL-5 $\dagger$	0.29 (0.25 – 0.33)	0.33 (0.22 – 0.43)	0.435
IL-6	1.5 (1.1 – 2.0)	1.1 (0.9 – 1.2)	0.136
IL-7	10.7 (9.7 – 11.9)	10.6 (9.2 – 12.2)	0.893
IL-8	24 (16 – 35)	15 (11 – 19)	0.101
IL-9	8.2 (7.2 – 9.2)	6.5 (5.7 – 7.5)	0.040
IL-10	5.5 (4.7 – 6.4)	4.6 (3.8 – 5.5)	0.165
IL-12p70	5.8 (4.9 – 6.9)	5.2 (4.5 – 6.1)	0.404
IL-13	0.85 (0.79 – 0.91)	0.81 (0.73 – 0.90)	0.448
IL-15	2.3 (2.1 – 2.6)	1.7 (1.5 – 1.8)	<0.0005
IL-17 $\dagger$	3.2 (2.6 – 3.7)	2.0 (1.6 – 2.4)	0.001*
TNF	160 (143 – 178)	130 (115 – 147)	0.025
Eotaxin	6.7 (5.6 – 7.9)	4.1 (3.1 – 5.5)	0.004
IP-10	590 (437 – 798)	401 (301 – 533)	0.119
MCP1MCA	75 (66 – 86)	71 (60 – 85)	0.647
MIP-1 $\alpha$	3.3 (2.6 – 4.2)	3.0 (2.3 – 4.0)	0.645
MIP-1 $\beta$	74 (62 – 89)	64 (53 – 77)	0.321
RANTES	2011 (1378 – 2934)	891 (545 – 1454)	0.016
bFGF	674 (596 – 761)	446 (384 – 518)	<0.0005
G-CSF	6.4 (5.0 – 8.2)	6.4 (5.2 – 8.0)	0.966
GM-CSF	4.4 (3.8 – 5.1)	2.4 (1.7 – 3.1)	<0.0005
PDGFBB	11.7 (9.9 – 13.7)	8.2 (6.1 – 11.1)	0.032
VEGF	160 (130 – 196)	150 (117 – 192)	0.722

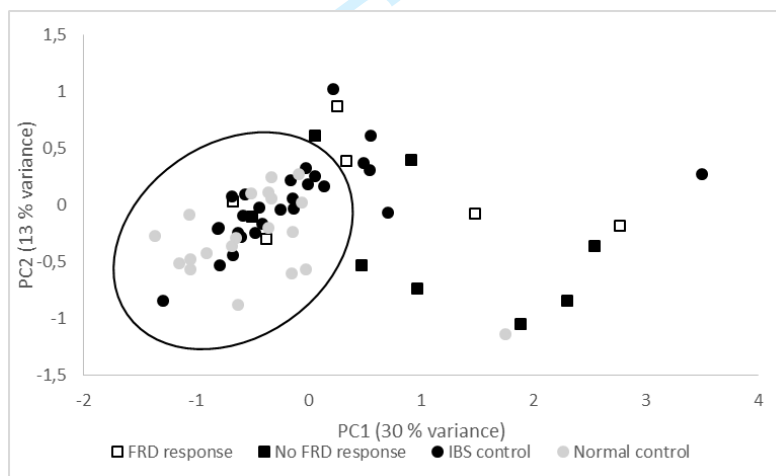

433 Values are mean (95% CI of mean) expressed in pg/mL of tissue supernatant. Logarithmic  
 434 transformation was applied to obtain Gaussian distribution in all cases except those marked

2  
3 438 **Figure 1.** Principal component analysis of 27-plex mediator measurement in rectal mucosa  
4  
5 439 from subjects with IBS w/wo fructose intolerance, IBS controls, and normal controls. Three  
6  
7 440 PC's were extracted accounting for a cumulated 55% of the variance. The plot shows  
8  
9 441 individual factor loadings of the two first components in a rotated solution. PC1 (30%  
10  
11 442 variance) represents an adaptive pro-inflammatory component with high contribution from  
12  
13 443 mediators like TNF, IFN $\gamma$ , IL-17, IL-4, and IL-2. PC2 (13% variance) represents an early  
14  
15 444 response pro-inflammatory component with high contribution from mediators like IL-8, IL-6,  
16  
17 445 IL-9, bFGF, and MIP-1 $\alpha$ .

**Table 1**
