ABSTRACT

Introduction In Nepal, one-fourth of the adult population has hypertension. Despite provision of comprehensive hypertension services through the primary healthcare system, huge gaps in treatment and control of hypertension exist. Our study explored the individual, interpersonal, health system and community-level barriers and facilitators affecting hypertension management in urban Nepal.

Methods We used a qualitative methodology informed by Kaufman's socioecological model, conducting focus group discussions with hypertension patients and their family members. In-depth interviews with hypertension patients, healthcare providers and municipal officials were also conducted.

Results We found that inadequate knowledge about hypertension and harmful cultural beliefs hindered effective treatment of hypertension. Interrupted medical supply and distrust in primary healthcare providers affected the poor's access to hypertension services. Poor communication between family members and gender norms affected adaptation of treatment measures. This study emphasised the role of family members in supporting patients in adhering to treatment measures and rebuilding community trust in primary healthcare providers for better access to hypertension services. The findings guided the development of a manual to be used by community health workers during home visits to support patients to control high blood pressure.

Conclusion The study highlights the importance of integrating various aspects of care to overcome the multiple barriers to hypertension management in urban settings in low-resource countries. Participatory home visits have the potential to empower individuals and families to develop and implement feasible and acceptable actions for home management of hypertension through improved adherence to antihypertensive medication, and behaviour change.

INTRODUCTION

One-third of the world's 30–79-year aged population have hypertension (1.28 billion), and two-thirds of them live in low and middle-income countries (LMICs).¹ Huge gap exists in the management of hypertension, particularly in LMICs, including Nepal.

WHAT IS ALREADY KNOWN ON THIS TOPIC

⇒ Interplay of individual, interpersonal, health system and community factors determine effective management of hypertension.

WHAT THIS STUDY ADDS

⇒ Despite availability of hypertension services poor and elderly patients had poor access.
⇒ Inadequate counselling to address wrong beliefs and misconception regarding hypertension hindered effective control of blood pressure.

HOW THIS STUDY MIGHT AFFECT RESEARCH, PRACTICE OR POLICY

⇒ To rebuild trust in primary healthcare facilities through improved counselling skills of healthcare providers and ensuring regular supply of hypertension medication.
⇒ To support individuals and family members in self-manage hypertension while encouraging routine physician follow-up for cost-effective management of hypertension without burdening the tertiary care.

A meta-analysis of surveys from 2005 onwards reported 30% of the patients with hypertension were on treatment and 10% were able to control hypertension in LMICs.² In Nepal, a quarter of the adult population have hypertension and only 28% were aware of their diagnosis, 11% of those diagnosed were on treatment and 4% had their blood pressure under control.³

Medication adherence, self-monitoring of blood pressure and lifestyle interventions have been effective in controlling blood pressure and reducing the incidence of cardiovascular events.⁴ Despite evidences on the effectiveness of lifestyle measures and antihypertensive medication, hypertension management remains challenging.^{5–7} Understanding of the complexity in managing hypertension demands a holistic approach considering the individual, and structural factors and how their interaction affects patient pathways.

Individual's beliefs or perceptions such as patients' understanding of the causes, symptoms, course of illness and effect of treatment affect adherence to behaviours related to hypertension management.^{8–9} Additionally, exploring the social context is important to understand patient behaviourism. Literature on behaviour change theory¹⁰ indicates that individuals and families can implement new knowledge for behaviour change when education interventions are combined with improvement in contextual factors. Despite the crucial role family has in assisting hypertension patients adhere to healthy behaviours,^{11–12} medication and follow-up visits¹³ their perspective on perceived facilitators and barriers are not sufficiently explored in urban Nepal.

Literature shows individual-level barriers such as poor knowledge about hypertension and its complications, difficulty sustaining lifestyle changes and comorbidities hinder blood pressure control.^{14–15} However, positive relationships with healthcare providers and family encouragement for lifestyle changes facilitate hypertension management.¹⁵ Lack of community resources for lifestyle changes and self-monitoring of blood pressure are known community-level barriers.¹⁵ Inadequate infrastructure, unaffordable medication, inadequate time and incentive for counselling and poor adherence to guidelines contribute to poor management of hypertension.¹⁶ These challenges relate to the design and the responsiveness of the health system to patient's needs in controlling hypertension. Also, there is insufficient contextual literature from urban Nepal on strategies to reach families in supporting patients adhere to proven treatment measures for hypertension.

Therefore, in this study, we explored facilitators and barriers affecting hypertension control in urban Nepal. The individual as well as community level facilitators and barriers that interact with the health system to affect hypertension control were explored and used to inform the design and implementation of a comprehensive approach to hypertension management intervention in urban Nepal.

RESEARCH DESIGN AND METHODS

Study design

We applied an exploratory qualitative research design using focus group discussions (FGDs) and in-depth interviews (IDIs) for data collection. Kaufman's socioecological model¹⁷ guided the study in understanding the facilitators and barriers to different aspects of hypertension control from the perspectives of different participants, including hypertension patients, their family members, primary healthcare providers, municipal official and ward representative. The socioecological approach has previously been used in understanding factors predicting cardiovascular risks in the USA¹⁸ and behaviourism promoting physical activity and healthy eating in the United Kingdom.¹⁹ It is acknowledged to provide a thorough understanding of complex health problems guiding

development of interventions to promote health.²⁰ The consolidated criteria for reporting qualitative research checklist were followed in reporting the study findings.²¹

Study setting

Budhanilkantha municipality is in Kathmandu valley, the capital of Nepal, and has a population of nearly 180 000.²² It is inhabited by the locals who have been living here for several generations and those who have moved and settled from other parts of the country. The adult literacy rate (82.1%) is higher than the national average (67.1%).²³ Urban areas like Budhanilkantha have one of the highest prevalences of hypertension (28.4%) in Nepal.²⁴

Budhanilkantha municipality runs four types of primary healthcare facilities, one municipal hospital, six health posts, two urban health centres and two basic health centres. There is a wide array of private pharmacies and hospitals within the municipality and several private and public specialised hospitals nearby. The basic and the urban health centres provide counselling, blood pressure measurement, primary treatment, including medication, referral and follow-up services for hypertension. In addition to these services, health posts provide basic pathology lab services.

Participant recruitment

Hypertension patients (n=36) and family members (n=33) were purposively recruited with aims to explore facilitators and barriers to hypertension management from the individual, family and social level. Healthcare providers from government (n=8) and private (n=4) health facilities, municipal official (n=1), ward representative (n=1) were conveniently sampled for interviews to explore facilitators and barriers to hypertension management from health system perspective. To explore heterogeneity in patient and family members' experience young and old (patients 42–89 years; family members 20–90 years), of both genders as well as individuals from different ethnicities were recruited.

We contacted and scheduled a visit to all public health facilities. During the visit, healthcare providers primarily responsible for providing hypertension care were interviewed. There are a limited number of healthcare providers in primary healthcare setting, and interviewing one from each facility was sufficient to gain understanding of healthcare delivery from that facility. We took appointments with municipal health official, and ward representative before visiting their office for interview. The healthcare providers and ward representatives were requested to link us with hypertension patients and family members. They gave us contact information of the community volunteers who helped us recruit hypertensive patients and family members from the community. The private healthcare providers were recruited from health facilities frequently mentioned by patient and family members during interviews. None of those approached refused participation. A signed informed

consent was taken from the participants. The information sheet was read to the illiterate participants before taking a thumbprint.

Data collection

Two female researchers (SaB and SwB), with more than a decade, experience in qualitative research conducted the interviews and focus groups. Recruiting participants with support from healthcare providers might have encouraged participants to expect the researchers to be care providers or higher level authorities coming to monitor hypertension care provision. However, it was explained to the participants that none of the researchers was care providers or was in a position to influence health service delivery.

Data were collected between January 2022 and June 2022, using FGD and IDI guides with different groups of study participants as shown in [table 1](#). Data were collected on a time and place chosen by the respondent.

1. FGD: we planned for four FGDs with hypertension patients and family members, which are considered sufficient to achieve code saturation gaining a comprehensive understanding of a range of new issues.²⁵ We were only able to conduct three FGDs for hypertension patients as it was challenging to collect them to one place due to distance and work priorities. For the FGDs, the participants were either invited to the health facilities or other community spaces.
2. IDIs: we conducted eight individual interviews with hypertension patients to supplement FGD data. Interviews with hypertension patients were conducted in their home and healthcare providers, municipal official and ward representative in their workplaces.

Kaufman socioecological model guided development of the tool and discussion with participants.¹⁷ The model held that patients' behaviour is influenced by individual, and environmental factors and their interaction.¹⁷ FGDs

and interview guides were developed by SBW with feedback on the draft from all the authors. SwB pretested the guide in a nearby municipality. Interviews and FGDs were conducted in Nepali language, lasted between 30 min and 45 min and were audio-recorded. After each FGD and interview, SaB and SwB discussed the findings noting new emerging themes and gaps in information and adjusted the guide accordingly. Examples of open-ended questions used for patients and family members: 'What do you understand about hypertension?', 'What went through your mind when you/your family member—were told you had hypertension?', 'What factors affected in management of hypertension?' 'What would help you to better manage hypertension?, What support do you receive/How do you support—in controlling blood pressure?

Example questions for healthcare providers, municipal official and ward representative were: 'How successfully is hypertension managed in the community?', 'What measures are taken to improve quality of hypertension services?', 'What community resources are available for patient to control blood pressure?' and 'What problem have you run into ensuring access to hypertension services?'

Data management and analysis

The audio recordings of the interviews and FGDs were transcribed verbatim. SaW and SwB both knowledgeable of the socioecological model inductively coded four transcripts (two healthcare providers' interviews and two hypertension patients FGDs) and compared codes achieving an intercoder reliability of 82.8%. Intercoder reliability was assessed for better reflexiveness and dialogue within the research team and to ensure quality of results.²⁶ Coding 10% of transcripts of different respondent types and an intercoder reliability higher than 80% is considered reasonable.²⁶ The disagreement in coding was discussed and mutually agreed before finalising the codebook. Then, SwB used the final codebook to code the remaining transcripts using dedoose qualitative data analysis software. When new codes emerged during coding, they were discussed before adding them to the codebook. New codes were added four times, and every time a new code was added, previously coded transcripts were reviewed. The emerging codes were summarised into categories in relation to the (1) individual (2) interpersonal (3) health system and (4) community-level factors affecting hypertension management. Descriptive write up and main interpretations were done by SaB and shared with all the team members for discussion, validation and adjustment.

RESULTS

The characteristics of the study participants are shown in [table 2](#). Patients with hypertension were on average 56 years old and family members were on average 42 years old. Majority of the participants were women (64%

patients and 88% family members), Newar ethnicity (28% patients and 48% family members) and homemakers (53% patients and 73% family member). Most of the patients had no formal education (56%) and 39%

of family members had secondary education. Most of the patients had a family history of hypertension (47%), were currently taking antihypertensive medication (69%) and sought hypertension care from private pharmacies

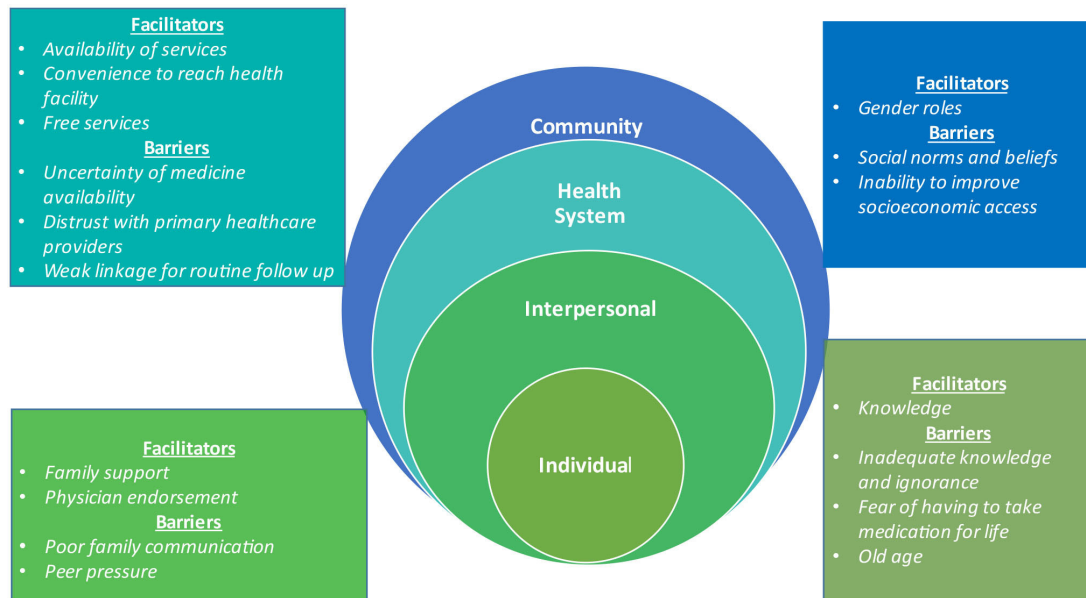

Figure 1 Multi-level facilitators and barriers to hypertension control.

(64%). Most of the interviewed family members were spouses (37%) or mother-in-law (33%). Most healthcare providers were women (58%) and paramedics (42%) (data not shown). Both the municipal official and ward representative were men (data not shown).

Facilitators and barriers to hypertension management

The barriers and facilitators to hypertension management were synthesised triangulating the perspectives of the hypertension patients, their family members, healthcare providers and municipal representatives. Figure 1 summarises the facilitators and barriers at individual, interpersonal, health system and the community level that emerged from the data. Knowledge was both a facilitator and a barrier, patients having knowledge adopted healthy behaviour, whereas patients with inadequate knowledge had poor adherence to antihypertensive medication. Inadequate knowledge also augmented social norms and beliefs regarding treatment measures affecting blood pressure control. Family support facilitated hypertension management, but its facilitating role varied with the level of interactions between family members.

Facilitators to hypertension management

Individual-level facilitator

Knowledge

When patients and family members were aware of the risk factors and hypertension control measures, they reported to adopt healthy behaviours. *Drinking alcohol and eating a lot of oily food affects our blood pressure... we should limit what we eat*—an 89-year-old male patient.

My mum (hypertension patient) preferred home remedies...eating bitter gourd to control blood pressure, but when she learned taking one medicine does good ... she has been taking medication regularly for four years—an FGD family members

Interpersonal-level facilitators

Family support

Patients who had family support had better adaptation of blood pressure reduction measures. For example, families encouraged healthy diet and modified cooking practices to adapt with the necessary dietary modification required for the hypertension patients. *They (family members) keep telling me you shouldn't eat this and that,.... don't eat oily and fried food*—a 43 years male patient.

We have reduced the amount of salt when cooking food—an FGD family member

Physician endorsement

Primary healthcare providers expressed hypertension patients came for follow-up care when their competence is validated by physicians in tertiary hospitals. *Sometimes they (patients) come back (for follow up) and tell us doctors in hospital told them we (primary healthcare provider) saved their life by referring them on time to hospital*—a public healthcare provider.

Health system-level facilitators

Availability of services

Availability of multiple services including physician consultant, medication titering and laboratory facilities in the same health facility was a major facilitator as it saved patients and family members time in seeking hypertension care.

Convenience to reach health facility

Proximity and convenient opening hours facilitated patients to go for routine blood pressure monitoring. *I would go to a private pharmacy nearby, the public health facility opens late and closes early*—43-year old male patient. Convenience was particularly important for older patients

with mobility problems. ... *as long as mum (patient) is able to walk, we go to the pharmacy nearby*—an FGD family member.

Free services

Most healthcare providers reported that provision of free blood pressure monitoring, counselling and antihypertensive medication encourages patients to use service from public primary healthcare, particularly among poor and elderly patients. *Those from low socioeconomic status... elderly who have no children to take them to hospitals, and those who don't have money to buy medicine come here (public primary healthcare facility)*—a public healthcare provider.

Community-level facilitator

Gender roles

Incorporating healthy behaviour into their daily routine was easier for men than women because men in Nepali society have lower responsibility for household chores and hence have more time for leisure. Furthermore, it is also more culturally acceptable for men to do physical activity. *Our father gets up in the morning, he is careful about what he eats... he goes for walks*—an FGD family member. Particularly, the men who are retired followed healthy behaviour because not having a daily job provides them time to focus on their health. *I have reached a certain age now, so I go for a walk in the morning, do not take much stress and eat less oily and salty food to balance the pressure*—a male FGD patient. In contrast Nepali women have responsibilities of household chores, resulting in less or no time and have social restriction for mobility. *I don't exercise... I don't have time... I am busy... go there, do that, just like that*—a female FGD patient.

Barriers for hypertension management

Individual-level barriers

Inadequate knowledge and ignorance

Ignorance about hypertension and its management can delay seeking care and adopting control measures. Many admitted that they do not regularly check their blood pressure because of not having symptoms. *When I have headaches, feel dizzy and have breathing difficulty... I go to a private pharmacy to check my blood pressure*—45 years female patient. Some patients who are on antihypertensive medication thought that they could stop medication after following a healthy lifestyle. *I used to take antihypertensive medication when I had headaches. After one year I discontinued and began doing exercise*—an FGD patient. While patients had the perception that antihypertensive medication alone was sufficient to control high blood pressure. *Hypertension patients drink alcohol, eat oily food alongside medicine. They believe nothing is needed when you are taking medicines*—an FGD patient. Some healthcare providers expressed that their patients ignored high blood pressure because they do not understand its consequences. *It is very difficult to make them understand... we ask them to go to see a doctor they ignore*—a private healthcare provider. Some patients reported that they delayed treatment believing high blood pressure to be fleeting and can be reduced easily

through dietary adjustment. *I didn't take medicine, because I thought that I could just stop drinking coffee and salty packaged food...*—42-year female patient.

Fear of having to take medication for life

Most patients and family members delayed initiating anti-hypertensive medication fearing having to take medication for life. *When the doctor told us to start medication and that it must be taken every day (for life), we were scared...*—an FGD family member. Patients considered medicines to be harmful and taking it everyday a nuisance. *We don't want to take medicine, after all medicines are chemicals ... I feel our body should not be exposed to harmful chemicals ... also I forget taking medicine because... I don't want to take it, but I guess I need to start taking it as there is no other way*—a 44-year female patient. Also, patients with low knowledge on benefits of taking medication had interrupted medication adherence. *I didn't want medication, ... but started again after three years and left once more ... I didn't think medication is necessary*—an FGD patient. Even after multiple encounters with healthcare providers fear of medication remained affecting optimal medication adherence. *She (hypertension patient) has high blood pressure for many years ... she usually maintains her diet... but takes hypertension medicine when she has headaches that are intolerable*—an FGD family member

Old age

Some older patients refrained physical exercise fearing it to be too arduous. *he sometimes goes for walkbut he fears his body and knees will not cope exercise*—an FGD family member

Interpersonal-level barriers

Poor family communication

Poor communication within family regarding hypertension and adherence status negatively affected medication adherence because family members would not know medicine ran out or reminded patients to take medication. *It has been 3 weeks since I stopped taking medication but no one in my family knows, if they know they will scold me*—44 years female patient. Poor communication also made it difficult to do the necessary dietary adjustments. *I have high (blood pressure), my wife has low, it is difficult to balance (diet) so we don't bring it up...*—an FGD patient.

Peer pressure

Peer pressure to drink alcohol and unhealthy food during gatherings often demotivated hypertension patients to follow healthier lifestyle. *Drinking and eating happens, ... when friends coax us. They say if you drink a little or eat just for one day... nothing will happen*—an FGD patient.

Health system-level barriers

Uncertainty of medicine availability

Gaps in antihypertensive medication at the primary healthcare facilities delayed treatment of hypertension patients. Many patients did not go to public facilities because they think that antihypertensive medication

is not available. *do they (public health facilities) give hypertension medication?...if we had known we would definitely go there*—an FGD family member. Some patients do not go for refill because of their previous experience of not being able to receive medication.

Distrust with primary healthcare providers

Primary healthcare providers expressed that the services were underutilised because patients and family members' do not trust on their competency. *People in the community think we know nothing,... they want to consult with a heart specialist*—a public healthcare provider. Lack of trust often arise because of irregular supply of anti-hypertensive medication at the health facility when they come for refill. Patients reported the lack of trust due to poor behaviour of primary healthcare providers and through that they compromise with the quality of hypertension services. *They (public primary healthcare providers) were not keen on providing services.... ignored my mother (patient) I got angry and shouted at them*—an FGD family member.

Weak linkage for routine follow-up

The ward representative expressed that patients were lost to follow-up at the primary level care because they did not receive proper counselling in hospitals. *Patients don't come to health centres... due to the high volume of patients, doctors in hospitals do not have sufficient time to explain treatment options and follow up care*—the ward representative. Only on rare occasions, hypertension patients with ongoing relationships with primary healthcare providers returned for counselling, follow-up care and medication.

Community-level barriers

Social norms and beliefs

Family members believed that inclination towards socially accepted norms and beliefs regarding home remedies (eg, eating bitter gourd) to control blood pressure interfered with hypertension treatment. *He (hypertension patient) ate boiled bitter gourd, or anything bitter, ...bitter food to reduce blood pressure level at first ...it didn't work so started medication*—an FGD family member. An elderly patient expressed that the lifestyle modification required unattainable self-discipline. *If people are ... religious and spiritual like 'saints',... having a lot of self-control... then blood pressure would be under control*—89-year-old male patient. Such fatalistic notion deter patients from even initiating behaviour change.

Inability to improve socioeconomic access

As expected, poor and elderly patients with comorbid conditions had poorer access to medication. *When you have both diabetes and hypertension, it is very difficult, medicines are so expensive most of us can't afford to buy them*—FGD family members. Though government provides some funds to underprivileged, healthcare providers have difficulty recommending patients due to absence of a well-defined process to identify the poor (eligible). *We are unable to support them (poor) because we are not from this*

community; we don't know whose economic condition is what—a public healthcare provider.

DISCUSSION

Several barriers and facilitators affecting hypertension management in urban Nepal were explored to inform the implementation of comprehensive approaches to hypertension management intervention. The major facilitators were, knowledge about risk factors and control measures motivating patients to adopt healthy lifestyle at individual level, family support at interpersonal level, availability of hypertension services at health system level and gender role enabling men to adopt healthy lifestyles at community level. Several important barriers were identified such as inadequate knowledge affecting medication adherence at individual level, peer pressure and poor family communication at interpersonal level, distrust in primary healthcare providers at the health system level and misconceptions regarding treatment at the community level. These findings have implications for future community interventions seeking to engage patients and families for hypertension control in Nepal and in similar LMICs, and we discuss these below.

We found that the individuals with adequate knowledge on hypertension were motivated to adopt healthy lifestyles and adhere to medication, which is also reported by previous studies from Nepal^{27 28} and LMICs.^{29–33} Consistent with findings from previous studies, motivation to adopt healthy lifestyles waned after starting medication in part due to insufficient knowledge about treatment measures.^{27 30 31 34} Patients and families could benefit from understanding the value of antihypertensive medication, and medication in tandem with lifestyle measures giving the best health benefit. Receiving information is insufficient to adopt healthy behaviours for blood pressure control.^{35 36} Paulo Freire's empowering education approach³⁷ engaging families over a period of time to critically analyse problems and its causes to develop and implement prioritised behavioural actions have been successful in managing chronic conditions.³⁸

Intersections of age, gender and income affect patients' ability to manage hypertension.³⁹ We found that elderly patients refrained from physical activity equating it to vigorous exercise, while female patients were unable to allocate time. In Nepal, women are primarily responsible for unpaid housework (cooking, cleaning, washing, shopping) spending on average 268 min per day in comparison to 56 min per day spent by men.⁴⁰ Tailoring physical activity to patient capacity may boost confidence in incorporating physical activity to control blood pressure.⁴¹

Adherence to antihypertensive medication is one of the keys to effective management of hypertension.^{42–44} Non-adherence to antihypertensive medication increases the risk of complications such as cardiovascular diseases (heart failure, myocardial infarction and stroke), which are increasing in Nepal.⁴⁵ The cultural belief that medicines are mainly for curing severe diseases and not for

reducing high blood pressure, an asymptomatic condition⁴⁶ has created delays in initiation and discontinuation among those who initiated in our study.

A strong belief in home remedies such as eating bitter food to reduce blood pressure delayed or caused discontinuation of medication. Previous studies have also reported preference for home remedies to manage hypertension and other chronic conditions in Nepal^{27,28} and LMIC.^{31,32,47} Preference for home remedies is due to their easy availability, perceived safety and endorsement from family and friends.²⁷ Misconception found in our study may be due to the high proportion of illiterate patient participants. Illiterates usually have poor access to information and knowledge,⁴⁸ impeding timely treatment and control of hypertension and its complications.²⁹ Increased knowledge on the benefits of medication could counteract the negative consequences of misconception.

Our study found patients receiving family support were able to adopt healthy lifestyles. Family support in ensuring recommended diet was also reported in a previous study from India.⁴⁹ It is an important factor for patients' blood pressure control.³² Improved interaction and providing authentic information to patients and family could enhance hypertension control. For example, family reminding patients to take medicine is known to improve adherence in South Asian countries.³⁴ However, the changing attitudes towards elderly and declining intergenerational support in Nepal⁵⁰ highlight further research on family's role in providing hypertension care. Also, families may be forced to prioritise the needs of breadwinners as opposed to elderly.⁵¹ The adult children and spouses as caregivers can be key stakeholders in the intervention, and they can play an active role in helping patients in monitoring blood pressure and adhering to medication and healthy behaviours.

The health system's inability to identify poor obstructed socioeconomic access to hypertension care. Poor patients may not have the financial resources to seek care and medicines.^{52,53} Reliable estimates of poverty are the basis for inclusive healthcare. Also consistent with previous studies from LMIC,^{34,54,55} patients distrusted the competency of primary healthcare providers. When patients doubt the quality of healthcare, they self-refer overcrowding the tertiary care.⁵⁶ The cost of travel and high fees at the tertiary care burden patients from low socioeconomic status.⁵⁶ Studies from Nepal have shown

patient discontinue treatment due to high cost of medicine and diagnostic tests.²⁷ Hypertension services in the public primary healthcare facilities are free, therefore ensuring uninterrupted supply of antihypertensive medication, and training healthcare providers on treatment protocols can improve access. Trained primary healthcare providers can personalise counselling based on patients' blood pressure measurements,⁴³ and regular positive interaction can help instate trust in the primary-level care.

Positive patient-provider interactions are important for hypertension management.⁵⁷ Our study identified poor patient counselling negatively affected patient follow-up. The high volume of patients in LMIC health centres is not conducive for positive patient-provider interaction³⁵ in lack of healthcare provider time and space. Patients not receiving counselling are likely to be non-adherent to treatment and routine follow-up.^{28,29,35,36} In Nepal, the female community health volunteers have traditionally channelled health information to the community.⁵⁸ Female community health volunteers may find participatory discussion difficult to implement,⁵⁹ but there is a possibility to leverage on the existing approach to bridge patient-provider communication gap by recruiting trained nurses for a comprehensive approach to hypertension management. Flexible and tailored approaches considering individuals' and family context are important when developing and implementing hypertension intervention.

Our results provide insights which can be applied globally. Research from other LMICs also show that adequate knowledge on hypertension services motivates patients to adopt treatment measures,³⁰⁻³³ and that addressing misconceptions^{29,46} and continued family support^{34,49} contribute to sustained behavioural changes. Rebuilding trust in primary healthcare providers^{34,49,55} is critical to ensure access to services for marginalised communities.⁵⁶ **Figure 2** highlights the recommendations drawn from our findings to guide future implementation of similar interventions in LMICs.

Strengths and limitations

The study's main strength was collecting the perspectives of different stakeholders: hypertension patients, family members, private and public healthcare providers and municipal and ward officials to gain a comprehensive

- Multi-component intervention, such as community mobilization and health system strengthening can rebuild trust in primary healthcare providers.
- Hypertension management requires tailored counselling considering individual's ability, family, and community context.
- Household visits can enable development and implementation of feasible strategies to address contextual barriers to hypertension management.
- Engaging family members can address detrimental misconceptions to enable behavioral change to manage hypertension.

Figure 2 Overcoming barriers to hypertension control—future perspective.

understanding of hypertension management in the community. Mixing different methods of data collection provided opportunities for clarification and triangulation of findings. The iterative process in data collection to achieve code saturation to gain comprehensive understanding of a range of new issues is expected to provide better internal validity. All focus groups and interviews were conducted by the authors (SaB and SwB) from similar cultural backgrounds as the participants. There were some limitations too. The heterogeneous (various socioeconomic background) sampling prevented us from understanding the intersection between evolving family roles, social class, gender, ethnicity, but we expect the participatory discussion during the intervention will allow further exploration. The findings are from a sample within one municipality and may not be generalisable to rural Nepal. Nevertheless, findings can be relevant for urban municipalities in similar low resource settings hoping to successfully manage hypertension.

Conclusion

Our study revealed the complexity of managing hypertension in urban Nepal. Inadequate knowledge and misconception on hypertension and medication affected adherence to treatment measures. Empowering families with knowledge on hypertension and its management was vital to optimise family support in home management of hypertension. The findings were and can be used in designing and implementing interventions to overcome the individual, interpersonal, health system and community barriers in managing hypertension.

Patient and public involvement

Participating hypertension patients, their family members, healthcare providers and municipal representatives were informed about the objective of the study and its implication. However, they were not directly involved in developing research questions and study design. The results of this study were discussed with the municipal representatives when developing the home visit manual.
